Growing AI into the Organization's DNA

Jweokk · 2026-10-18 · v2.0.8

Models are no longer scarce. People who can grow models into their organizations are.
From the 95% project failure rate to DeepSeek's 160-person innovation density —
this book explains what an AI-native organization is, what the evidence says, and how to build one.

Contents

01 Preface: Why I Wrote This Book

02 Chapter 1 The Rise of AI-Native Organizations — Starting from the 95% Failure Rate

03 Chapter 2: What Is an AI-Native Organization — Band-Aid AI vs. AI-Native DNA

04 Chapter 3: The Evidence — What the Empirical Research Says

05 Chapter 4: Rebuilding Organizational Structure — From Hierarchy to Network

06 Chapter 5: Redesigning Workflows and Decisions

07 Chapter 6 Incentives and Talent: The Hardest Variable to Rebuild

08 Chapter 7: Case Studies — AI-Native Organizations in China and Around the World

09 Chapter 8 Building Your AI-Native Organization: An Action Playbook

10 Chapter 9: Challenges, Risks, and the Future

11 Chapter 10 Industry Guide: AI-Native Transformation Across Ten Industries

12 Afterword: A Living Book

13 Appendix A: Case Index and Sources

14 Appendix B: Key Metrics for AI-Native Organizations

15 Appendix C: Version History and Update Notes

Preface: Why I Wrote This Book

In the summer of 2026, two headlines read side by side made the answer almost obvious.

The first: MIT's NANDA lab released *The GenAI Divide*, reporting that over the past three years, companies worldwide have burned $30–40 billion on generative AI, and **95% of organizations have gotten no return that could be written into their financial statements**. For customized enterprise AI tools, the funnel from evaluation to pilot to production is 60% → 20% → 5%.

The second: DeepSeek built a trillion-parameter model with 160 people; Klarna shrank its workforce from 5,527 to 3,422 employees over three years while revenue kept rising; at Anthropic, Claude wrote more than 80% of the production code merged; and a company called Cursor reached $4 billion in annualized revenue with 300 people.

On one side, 95% of AI projects come to nothing. On the other, a small cluster of organizations are levering enormous output with tiny teams.

Put the two together and the answer is not hard to guess: **models are no longer scarce. What is scarce are the people who can grow models into their organizations.**

What I've Been Researching

About 90% of the public discussion around "AI transformation" tells you how to **add AI capabilities** to your existing organization: buy a Copilot, run a few dozen training sessions, appoint a chief AI officer. But what is actually happening runs on a different track — **letting the organization itself grow AI into its DNA**. These two things are worlds apart.

This book sets out to study, end to end, a systemic change that is already under way but does not yet have a name: the AI-native organization. It clarifies three things:

- **What it is**: the essential difference between AI-native organizations and "AI transformation" — band-aid AI vs AI-native DNA;

- **The evidence**: what the empirical research from HBS, INSEAD, the WEF, and Tencent Research Institute actually says;
- **How to do it**: restructuring organizational form, restructuring workflows, restructuring incentives — plus a zero-to-one playbook.

All data and case studies in this book are cited in Appendix A. The work of compiling was itself a form of learning, and I have tried to make every citation verifiable; if anything is missing, corrections are welcome.

How This Book Was Auto-Written

This book was not written in a single pass. It is a "living book," powered by an automated content pipeline:

1. **Daily accumulation**: an automated system scans global information on AI deployment and organizational change every day, distilling, translating, and structuring high-quality content into a knowledge base;
2. **Deep research**: on top of the material already in the knowledge base (12 core concept articles plus 20+ case articles), the first edition underwent three further rounds of deep research — landmark international cases, raw data from authoritative reports, and failure cases and construction methodologies — with every source verified one by one;
3. **Weekly updates**: every week since, newly added knowledge base content is automatically merged into the relevant chapters, the version number increments (v1.0.0 → v1.0.1 → ...), the PDF is regenerated, and it is automatically deployed to the website;
4. **Continuous evolution**: whatever each update changed or added is recorded in Appendix C and in the repository's CHANGELOG, at a glance.

The process of writing this book is itself the book's best case study: **one person + an automated information pipeline + continuous weekly iteration produced something a traditional publishing process would take months to complete — and could never keep updated.** That is the AI-native organization in miniature, applied to content production.

Acknowledgments

This book's format and open publication model were inspired by XDash (Fan Bing)'s book, *Frontline Deployment Engineer: The Playbook for Delivering Customer Value in the Age of AI* *(https://github.com/xdash/FDE-the-Guidance-Book-of-Forward-Deployed-Engineer)* (https://github.com/xdash/FDE-the-Guidance-Book-of-Forward-Deployed-Engineer). The pattern of free public full text, synchronized reading via a GitHub repository and website, whole-book PDF download, and appendix-sourced citations is an open-source knowledge practice worth promoting. Special thanks.

Much of the material in this book comes from public industry research, media reports, and practitioners' sharing, and I have done my best to cite sources in Appendix A. If any citation is missing or there are copyright concerns, please contact weokk2025@gmail.com and we will correct it immediately.

Reading Guide

- To quickly judge whether your company counts as AI-native: read Chapter 2
- To see evidence rather than opinion: read Chapter 3
- To get hands-on: read Chapter 8, together with the workflow restructuring in Chapter 5
- To understand why most transformations fail: read Chapter 9
- To go through all the case studies: read Chapter 7

This book is free and open; feel free to share it. The value of knowledge lies in its flow, not in hoarding it.

Chapter 1 The Rise of AI-Native Organizations — Starting from the 95% Failure Rate

1.1 A Number That Has Been Misread

Over the past two years, the most widely circulated AI statistic on the Chinese internet has been: "95% of enterprise AI projects fail."

The claim is both right and wrong. It comes from MIT's NANDA lab's July 2025 report, *The GenAI Divide*.[1-02] The report's precise framing has two layers:

- **By organization**: 95% of organizations got zero return[1-02] from their generative AI investments;
- **By tool funnel**: of customized, task-specific enterprise AI tools, only 5% make it to production deployment — 60% of organizations evaluated such tools, 20% entered pilots, and 5% reached production.

General-purpose chat tools (ChatGPT, Copilot, and the like), by contrast, convert from pilot to deployment at roughly 83%[1-02] — they are not failing.

This detail matters enormously: **what "failed" is not all AI projects, but the customized systems deeply embedded in business processes that set out to replace core ways of working.** People who used AI casually gained efficiency; organizations that seriously reworked their businesses mostly came to grief. That is the "GenAI divide" the report describes — a polarization of outcomes between buyers (enterprises) and sellers (AI companies).

Figures from other institutions paint the same picture:

- Gartner predicts that by the end of 2025, at least 30% of generative AI projects will be abandoned after proof of concept (PoC)[1-07];
- Gartner predicts that by the end of 2027, more than 40% of agentic AI projects will be canceled, with soaring costs the primary reason;
- IDC: 88% of AI agent pilots fail to graduate into production;
- An industry survey: for every 33 pilots launched, only about 4 successfully make it into production;

- Professor Fang Yue of CEIBS (China Europe International Business School) (2026): more than 90% of companies worldwide have launched generative AI pilots, but fewer than 41% of projects have truly crossed the experimental stage to create value at scale — he calls this phenomenon "pilot boom, value void."

Note that these numbers use entirely different measures (organizational zero-return rate / PoC abandonment rate / pilot-to-production conversion rate), yet they all point to the same structural fact: **the gap from pilot to production is real, and it is pervasive.**

1.2 Why Pilots Succeed and Production Fails

A strange, repeatedly observed phenomenon: AI projects that demo beautifully in the pilot phase collapse the moment they enter production.

The reason is that pilot success usually depends on humans "quietly patching things up" — supplying missing context by hand, bridging system failures, absorbing risk. Once those patches are stripped away in production, the AI immediately fails. Three layers specifically:

1. **Broken context**: the AI can only see a narrow slice of enterprise information and cannot reason across systems or across time; unstructured documents (PDFs, contracts, handwritten forms) are entirely invisible to it. In a demo this can be hidden; in production there is nowhere to hide.
2. **Fragile integration**: pilots are usually read-only; production requires the AI to write back to systems, trigger workflows, and act across dozens of applications. Point-to-point fragile integrations are immediately exposed — "read-only intelligence cannot act."
3. **Failed governance**: at pilot scale, human review can catch everything; at production scale, the "human in the loop" becomes a bottleneck rather than a safety valve, and missing audit trails breed risk aversion and frozen projects.

The few organizations that did make it into production (about 5%)[1-02] made three different decisions: **build shared enterprise context first, standardize AI's "action layer," and embed governance into systems rather than leaving it to manual management.**

1.3 Another Group Running Hard in the Opposite Direction

Just as the vast majority of organizations are stuck in Pilot Purgatory, a small cluster of organizations are operating on a completely different logic:

- **DeepSeek**: 160 people built a trillion-parameter model, versus roughly 3,500 at OpenAI, 3,000 at Anthropic, and 8,100 at DeepMind;
- **Klarna**: full-time employees fell from 5,527 in December 2022 to 3,422 in December 2024 (-38%), while revenue kept growing over the same period and revenue per employee reached 3.6 times its 2022 level;
- **Shopify**: after cutting 20% of staff in 2023, headcount held flat for several consecutive quarters while revenue per employee rose from $1.1 million to $1.52 million;
- **Anthropic**: Claude writes more than 80% of merged production code, and per-engineer quarterly code output is 8 times the baseline;
- **Cursor**: about 300 people, annualized revenue from $1 billion to $4 billion, revenue per employee of $3–13 million;
- **Duolingo**: zero full-time layoffs, content capacity up about 11 times in two years;
- **Airbnb**: AI co-writes the code produced by 60% of engineers, and AI customer support resolves 40% of issues without escalation to humans.

What these organizations share is not "using AI" — 88% of companies using AI[1-03] have not achieved this. What they share is this: **AI is not a band-aid applied to a legacy organization; these organizations redesigned themselves around AI.**

1.4 The Scarcest Evidence of All: Causality

Everything so far is correlation and case studies. You could reasonably object: maybe these companies were simply stronger to begin with?

In 2026, researchers at INSEAD and Harvard Business School ran a rare randomized controlled experiment[1-33] that pushed this question from correlation to causation.

They recruited 515 high-growth startups[1-33] and assigned them at random: **every company** received equal API credits, access to frontier models, and technical training. The only difference: the treatment group additionally received case-study materials on how AI-native companies reorganize their production processes, teams, and business models, while the control group took only an ordinary entrepreneurship course.

With tools, skills, and budgets fully equalized, merely changing the "organizational search space" — letting the treatment group see what AI-native companies look like — produced:

- **+44%** more AI use cases discovered/used (concentrated especially in high-leverage areas such as strategy and product development);
- **+12%** more tasks completed; **+18%** likelihood of acquiring paying customers;
- Revenue **1.9×**[1-33];
- External capital needs actually fell **39.5%**.

The paper introduces a core concept: the **"mapping problem"** — what limits AI's returns is not technology costs or skills, but the cognitive bottleneck of discovering where and how AI creates value within one's own production processes.

This is a conclusion worth chewing on repeatedly: **handing employees tools is not the same as reengineering processes; simply knowing what an AI-native organization looks like can itself produce a 1.9×[1-33] difference in revenue.** That is why this book is worth reading, and why XDash's FDE book is worth reading — knowledge of organizational form is currently the highest-ROI knowledge there is.

1.5 This Chapter's Core Judgment

Put the three sets of facts together:

1. 95% of organizations get zero return from AI investment;
2. the 5% who succeed share one trait — they redesigned the organization around AI;
3. merely "knowing what the winners look like" produces a 1.9× revenue difference.

The conclusion is already clear: **models are no longer scarce; what is scarce are the people who can grow models into their organizations.** In the chapters that follow, we will see what such an organization looks like (Chapter 2), what the evidence says (Chapter 3), how it operates (Chapters 4–6), who has already done it (Chapter 7), and — how you can do it (Chapter 8).

Chapter 2: What Is an AI-Native Organization — Band-Aid AI vs. AI-Native DNA

2.1 The Core Proposition: You Are Not Building an AI-Native Organization — You Are Applying AI as a Band-Aid to a Legacy One

> **No matter how well you apply the band-aid, the bone underneath is still the old bone.**

A company gives AI tools to every department, runs dozens of training sessions, and hands out incentives — and at the year-end review, adoption is below 15%. The tools were bought, the training was done, the incentives were paid, yet the organizational structure, decision processes, and evaluation criteria are all still traditional. AI is just a band-aid stuck onto a legacy organization.

This is the dividing line between "AI transformation" and "AI-native."

Alexander Puutio (Forbes) offers a sharp conceptual framework: **AI-native is, in essence, a reversal of the design order.**

- Traditional organization: design processes for humans → software assists and accelerates;
- Digital-native: design around software → humans still produce the primary value;
- **AI-native: first ask what AI can reliably do → then design human roles around AI.**

"An AI-native organization is not one that uses AI tools — it is one built around them."

This definition can test any "AI-native" claim. The criterion is not "how much AI is used," but: **if the organization were designed from scratch tomorrow, would AI be written into the blueprint?** If the answer is no, it is only a band-aid.

2.2 Three Common Traits

Drawing on the practices of Chinese companies including Alibaba, Huawei, Lenovo, Feishu, and Transn, AI-native organizations share three traits that recur again and again.

Trait 1: AI-informed decisions replace experience-based decisions. Traditional organizations decide based on Old Wang's experience and Director Zhang's gut. In an AI-native organization, as business data flows through the underlying systems, AI automatically performs analysis and early warning, and decision recommendations are pushed directly to the responsible person — decisions are based on data, not feelings. Huawei's approach is to embed AI across the entire data lifecycle, making intelligent analysis the default capability of its data platform: "You don't go looking for it; the system delivers it to you."

Trait 2: Business flow and workflow are unified. In traditional companies, the business flow lives in the CRM and the workflow lives in DingTalk or Feishu; project progress is in system A, meeting minutes in system B, approvals in system C — everything is carried across by hand. Feishu's approach is a collaboration suite that connects IM, documents, and business flow, with AI intervening in project milestones in real time rather than summarizing afterward.

Trait 3: Making expertise reproducible. In a traditional organization, when the top salesperson leaves, the expertise leaves with them. In an AI-native organization, AI automatically records decision logic and updates business rules, turning one person's expertise into a reusable organizational asset. Transn founder He Enpei puts it this way: "Rather than wait for employees to become AI experts, it is better to grow AI capability into the organization." Individuals come and go; organizational capability stays.

2.3 Historical Analogy: The Electricity Revolution of the 1880s

In the 1880s, factory owners bought electric motors to replace steam engines, but factory layouts, assembly line designs, and the division of labor did not change — and efficiency did not improve. Electricity only changed the power source; the mode of production was still steam-age. The real winners were the people who redesigned factory layouts, invented the assembly line, and gave every workstation its own power supply.

Today everyone is installing AI, but few are genuinely redesigning their own factories.

This analogy yields a second definition of the AI-native organization: **it is not a change of power source, but a redesign of the mode of production.** Going from horse-drawn carriage to automobile is not about bolting an engine onto a carriage — you have to reinvent the wheel, design the steering wheel, build the roads, and set the traffic rules. The entire ecosystem must be reconstructed.

2.4 A Misconception That Must Be Corrected: The CAIO

Chinese-language internet media widely repeat the claim: "Gartner predicts that by 2025, 90% of large enterprises will have a Chief AI Officer (CAIO)."

This is a misquote — there is no evidence for it. The verifiable original Gartner prediction (published in 2023) is that by 2025, 35% of large organizations will have a CAIO reporting to the CEO or COO. The figure "90%" has no corresponding source anywhere on Gartner's website.

The "CAIO trap," however, is real — the argument just needs to be corrected: **AI is not one director's job; it is the whole company's job.** If you create a Chief AI Officer position while leaving structure, decisions, and incentives untouched, the CAIO is a general with no army — the same structural trap as the traditional enterprises that created "Internet directors" in 2005: the director spent three years unable to move anything and finally quit. The Internet was never one director's job, and neither is AI.

2.5 Three Easily Confused Concepts

Puutio goes to great lengths to distinguish three concepts, because many companies use them to impersonate one another:

Concept	Core trait	Typical trap
Digital-native	Built around cloud + SaaS; humans remain the primary producers	Thinking that deploying Copilot makes you AI-native
Platform organization	Coordinates an ecosystem, optimizes connections	Thinking that having network effects makes you AI-native

Concept	Core trait	Typical trap
AI-native	Redesigns internal workflows around AI systems, optimizes production	Flattening without enough AI infrastructure = chaos

Plus the three categories of tools in an AI-native organization:

1. **Vendor-embedded AI services** (Copilot and the like) — the easiest entry point, but not enough to count as AI-native;
2. **External agentic AI systems** — standalone tools for cross-application, multi-step automation;
3. **Internally built tools** — built on proprietary data and processes, becoming a sustainable advantage.

2.6 Employee Roles and Strategic Principles

In an AI-native organization, the definition of employees' roles changes fundamentally:

> "Employees no longer define their value primarily by the volume of work they personally produce... they create value by orchestrating systems that produce work."

Humans shift into orchestration and product-management roles; the most valuable employees understand both the boundaries of AI capabilities and the limitations of the systems; performance standards shift from "how much work did you do" to "designing better work."

Puutio states a clear and stern strategic principle: **"Don't involve people where people aren't needed."** This means:

- Investment decisions are made only around AI-driven ways of working;
- Tools and roles that exist only to manage human work rather than system performance should be questioned;
- Core processes are defined around tasks AI can execute reliably.

2.7 Building from Scratch vs. Retrofitting: A Real Debate

On whether "an AI-native organization can be transformed from a traditional one," there are two positions:

- **Puutio (strict-definition camp)**: "An AI-native organization is necessarily a greenfield effort. Retrofitting rarely works."
- **Shmool (feasible-path camp)**: A CEO who subtracted inside an existing organization, collapsing the traditional hierarchy (VP → director → manager → team lead) into a single-layer AI-native organization — successfully (details in Chapter 4).

A reconciliation of the two: Puutio is talking about the strict definition (what a true AI-native organization is), Shmool about a feasible path (how to get close to it). Retrofitting may achieve "quasi-AI-native" — close to, but not identical to, designing from scratch. The difference lies in the ability to "change the decision order": starting from zero allows you to re-ask "what can AI do" from the beginning; retrofitting means redefining while dismantling the old structure.

2.8 The Checklist: Are You Applying a Band-Aid or Growing the Gene

Ask yourself five questions:

1. **Design order**: Do you first ask "what can AI reliably do" and then design human roles, or do you have processes first and stuff AI in afterward?
2. **Decision basis**: Are decisions based on data pushed automatically plus human judgment, or on human experience with AI on the sidelines?
3. **Business flow and workflow**: Are the two systems unified, or are you still carrying data across by hand?
4. **Experience retention**: When the top salesperson leaves, does their expertise stay?
5. **Evaluation criteria**: Do reviews still look at hours worked and volume of output? (detailed in Chapter 6)

If all five answers point to "old structure," you are applying a band-aid. If even one or two have started to shift, you are already on the road to growing the gene. **An AI-native organization is not an "upgrade" but a "rebirth" — and it can be reborn in stages.** The next chapter looks at the evidence.

2.9 The Myth of AI Ubiquity — The Barbell Distribution and "Pushing AI into the Background"

Vasuman Moza (a former Meta engineer and founder of Varick Agents, which deploys AI agents for large enterprises with $500M+ in annual revenue) spent a year embedded inside large companies and found that no matter whether a team has 50 people or 5,000, handing the best AI tools to every single person always ends in a "barbell":

5%–10% of people become power users, 20% use AI occasionally but crudely, and the remaining 70% barely use it at all. One large enterprise that had just signed an eight-figure-dollar annual AI contract even found that **10% of its employees consumed 90% of its tokens.**

This explains the paradox this book keeps returning to: McKinsey surveys show that 88% of organizations use AI in at least one business function, yet only 6%[1-03] of enterprises earn more than 5% of their EBIT from AI. Model capability jumps every few months; organizational productivity does not automatically keep up.

Moza's more radical judgment is that this gap will not close by itself, and most employees will very likely never become AI-native users — because using AI well is a craft (knowing when to clear context, when to crystallize repetitive work into skills, when to hand judgment to the model, and when to write deterministic code). AI vendors' product roadmaps revolve around the most active frontier users, so the bar for "using AI well" keeps rising; the AI experts inside companies have no incentive to share — the gap itself is their advantage.

His strategic pivot: **first accept that most people will not become AI-native.** Let that 5%–10% of power users keep running ahead, and distill the skills, workflows, and agents they figure out into a shared library, where ranking is the reward. For the remaining majority, **push AI into the background** — embed agents into the systems employees use every day (Salesforce, NetSuite, Dynamics): invoices processed automatically, data entered automatically, processes flowing automatically, with humans called in to approve, reject, or modify only when the machine is unsure

— employees may not even realize they are "using AI." The metrics change accordingly: instead of asking "how many employees used AI this month," ask "of the work completed today, how much was done entirely by humans, how much by human–AI collaboration, and how much ran automatically."

This is structurally identical to Transn's judgment in Chapter 7: **rather than wait for employees to become AI experts, grow AI capability into the organization.** (Two caveats: the 5/20/70 distribution comes from the author's own client observations, not a large-sample benchmark; and embedding agents into enterprise workflows is precisely the service he sells.)

The same structural framing comes from Zilbix's *Enterprise Operating Models in the Agentic Era*: the past two years of "layering tools on top of existing structures" produced exactly the gap described above. The agentic era exposes three fractures — **unclear decision rights** (cross-functional agents without governance are either confined to low-value tasks or run unsupervised), **the talent model** (employee value shifts from executing tasks to orchestrating systems, interpreting outputs, and making judgments), and **the data architecture** (fragmented data blocks real-time access). An AI-native operating model is therefore three-dimensional: leadership actively sponsors the operational transformation (not merely approving budgets), decision rights with accountability and audit trails, and processes redesigned for AI participation (rather than retrofitted) — built on an AI-ready data foundation.

2.10 Buying AI Features vs. Building AI-Native Capability

A data point from HR technology puts this question on the table: more than 70% of Chinese enterprises claim to have deployed AI HR tools, but fewer than 15% have achieved an organizational capability leap[8-72]. "Sticking an AI label on a legacy system" and "rebuilding the organization's memory hub and decision nerves" are two entirely different paths: the former is consumption — it compounds nothing; the latter is investment — the more it is used, the more it understands the enterprise.

AI-native capability can be measured with a three-layer architecture:

- **Organization-wide memory**: data assets shared across modules and scenarios — candidate tags, onboarding profiles, and talent reviews reused across the full chain, breaking down data silos;

- **Proactive initiative**: the system finds people instead of people finding the system — an agent judges "what should happen now" from real-time data (a candidate not interviewed for three days → reminder; two no-shows → lower intent score and recommend alternatives) rather than executing fixed scripts;
- **Continuous evolution**: every manual correction is written back into the underlying context asset layer, forming a data flywheel. The formula: **AI talent density × AI collaboration depth = organizational intelligence compounding**.

Why can't a legacy system leap forward by "adding an AI module"? Three barriers. First, **architecture debt**: recruiting, HR, and performance each have independent databases — a cross-database query needs 3 databases and 5 field mappings and takes more than 8 seconds, so AI can only be bolted on. Second, **interaction paradigm conflict**: menus-plus-forms coexisting with dialogue-plus-recommendations raises cognitive load instead of lowering it (one financial enterprise saw feature usage *drop* 18% after adding an AI assistant). Third, **the data-permission gap**: permissions are designed per module, so AI cannot read or write across modules — either rebuild the permission system (prohibitively expensive) or give AI low privileges (confining it to edge tasks like summarization and visualization).

How do you verify whether a system is truly "AI-native"? Four questions. Ask the AI, "Which department is Zhang from last year's campus recruiting in, what's his performance, and what internal position would he fit?" — if you must manually specify the data source, it's not integrated; a direct answer with sources is real integration. If a resume sits untouched for 48 hours, does the system react (push to the interviewer, remind, flag low intent)? After three months of continuous use, does recommendation accuracy improve with manual corrections (stuck at 40–50% = fixed algorithm; rising = learning)? Can you define enterprise rules in natural language ("tech roles must have a final interview with the CTO") instead of filing tickets and waiting for version releases?

The path scales by size: organizations of 200–500 people build their first data flywheel in recruiting and reuse the tags through onboarding and probation; 500–2000 build cross-scenario collaboration by connecting the recruiting–HR–talent chain on a shared data foundation; 2000+ sink enterprise context into an organizational capability platform that speaks "management dialect." The smaller you are, the more

you should start with a single point of breakthrough rather than rolling out every module at once. (The talent data cited here is vendor-reported and treated as official claims; see Appendix A.)

2.11 The Enterprise World Model: The Cognitive Foundation of AI-Native Operations

A large model possesses public common sense but lacks enterprise-specific knowledge. It knows that "when inventory runs low, you usually reorder," but not that "at this company the reorder threshold is 120% of safety stock, orders above 500,000 yuan need a VP's signature, and weekend reorders go through an emergency channel." Wei Wei and colleagues (Peking University HSBC Business School) define this absence as a missing "enterprise world model" and propose a four-layer architecture to build it[8-92]:

- **Theory**: the business knowledge and management experience humans express in natural language — the cognitive source of the world model;
- **Ontology**: theory translated into machine-understandable concept frameworks, rules, and operational definitions — the hub that turns what humans know into what machines understand;
- **Instances**: the real data held in enterprise systems (transaction records, customer information, equipment parameters);
- **Skills**: executable operations bound to the ontology, which upgrade the world model from read-only to read-write.

Internally, the ontology is assembled from four atomic elements — **entity, property, relation, behavior** — which the author calls a minimal complete set: inheritance is a special relation, business rules are triggered behaviors, and permission control is a system-level behavior attached to an entity. The multi-ontology principle then surfaces an often-overlooked management truth: **many cross-departmental disagreements are not about facts but about using different ontologies to interpret the same facts** — sales says "this customer matters" (revenue-contribution ontology) while risk says "this customer is high-risk" (credit-risk ontology), and both see identical facts. The author identifies Palantir Foundry as a complete engineering implementation of this four-layer architecture. More important is the claim that the large model acts as a "universal translator"

between the four layers, shifting world-model construction from top-down manual building to intelligent growth from any starting point: an enterprise can begin from a business document, a database, or a piece of existing code and let the model fill in the other layers and cross-validate them.

The strategic implication is sharp: since the cost of acquiring model intelligence is trending toward zero, differentiation can only come from the enterprise's own world model — **the speed at which that world model evolves is the enterprise's moat.**

2.12 Operating Discipline: Six Dimensions Between AI-Assisted and AI-Native

The most practical way to tell "AI-assisted" from "AI-native" is not the tool stack but operating discipline[8-90]:

Dimension	AI-Assisted Team	AI-Native Team
Role of AI	Productivity add-on layered onto the existing workflow	Core participant in planning, execution, and review
Specification quality	Informal; engineers fill in the gaps	Explicit; written for both humans and agents
Context management	Tribal and implicit	Structured, documented, accessible at the point of work
Review culture	A downstream quality gate	Continuous validation integrated into delivery
What is measured	Output volume (PRs, commits, velocity)	System quality (defect escape rate, rework, stability)
Learning loops	Individual; lost when people leave	Systematic; encoded in templates, standards, guardrails
AI governance	Ad hoc; permissions set by default	Deliberate: bounded scope, audit trails, approval paths

In one sentence: **the AI-assisted team runs faster on the same track; the AI-native team rebuilt the track**[8-90]. This line also explains why point-level speedups fail to compound. ByteByteGo's interview with Meta's ads-systems architect captures the shift in the scarce resource: once generation has near-zero marginal cost, "evaluating quality, setting direction, and making hard trade-offs" become the bottleneck, and leadership capability shifts from delegation to orchestration[7-75] — which is exactly the gap the next chapter examines: what lies between tool ubiquity and organizational returns.

2.13 Maturity Levels: The "Perilous Leap" from "+AI" to "AI+"

In September 2026, the World-Class Enterprise Research Institute and Business School of Renmin University of China, together with Lenovo (Chinese: 联想), published *The AI-Native Organization Transformation Guide* — the first attempt to break "AI-native organization" down from a buzzword into self-assessable levels and executable steps[8-96]. It defines an AI-native organization as one that deeply embeds AI into its business model and work processes so that agents become a new form of organizational productivity, jointly forming a human-intelligence co-creation organization with carbon-based employees. The path is expressed as five maturity levels: Level 1, localized "+AI" experiments; Level 2, broad "+AI" application; Level 3, building a hybrid AI foundation; Level 4, "AI+" operational redesign; Level 5, AI-native maturity. Lenovo calls the leap in the middle the "perilous leap," with a simple analogy: adding power tools to a craft workshop is still "+AI"; only when the assembly line is built around machines is it "AI+".

The method is condensed into a "golden five-step" sequence — top-level planning, value-led prioritization, silicon-based buildout, carbon–silicon fusion, and flywheel evolution — supported by a three-tier benefits-management system of scenarios, projects, and programs, organized around revenue growth, cost savings, and efficiency gains so that value can be measured and attributed[8-96]. Three points are worth remembering: it reframes the focus from "tool deployment" to "organizational redesign"; its two signature concepts — "silicon-based buildout" and "carbon–silicon fusion" — treat digital employees as part of the establishment rather than as projects; and it explicitly keeps the first-phase goal on operational value (revenue, cost, efficiency) while exploring strategic value (direct-to-customer models, new growth engines) in parallel rather than betting on it all at once.

This ladder runs in the same direction as the test proposed in this book: **maturity is not measured by what you bought, but by whether the organization already orchestrates, evaluates, and develops AI as an existing member of the workforce.** That is also where grading matters — it turns "where are we on this ladder?" into something that can be disclosed externally, and therefore into something peer pressure can push forward, rather than a one-off internal discussion.

Chapter 3: The Evidence — What the Empirical Research Says

The first two chapters were about concepts and cases. This chapter looks only at evidence: what academic research and authoritative institutions' data actually say about AI-native organizations. To avoid "cherry-picking evidence that favors our argument," I will also list the limitations of every study.

3.1 HBS's *AI-Native Firms*: The Strongest Firm-Level Evidence

AI-Native Firms (HBS Working Paper 26-090, 2026)[1-29], a working paper by Harvard Business School's Rembrand Koning and INSEAD's Hyunjin Kim and colleagues, is currently the hardest first-hand evidence at the firm level.

Method: All 2,891 YC startups from the W20–F24 cohorts (11 batches), plus 41,214 US VC-backed startups from PitchBook[1-29], linked to micro-level labor data and compared against non-AI startups of the same industry and period.

Core findings:

Dimension	AI-native firms vs. non-AI peers
Team size	**~25% smaller** (YC firms roughly half the size after three years)
Share of engineers	~13 percentage points higher
Entry-level employees	~15% fewer
Senior employees	~20% more
Management layers	**Half a level flatter**
Managers	~15% fewer
Funding / valuation	Comparable → ~20% more funding per capita, higher valuation per capita

In one sentence: **AI-native companies are smaller, flatter, more engineer-dense, and more senior, with comparable valuations — and higher output per capita.**[1-29]

The paper's most important theoretical contribution is distinguishing two channels:

- **The process channel**: AI as an internal production tool that changes how employees do their work (agentic coding, AI customer service, automated sales) — this is where most existing research focuses;
- **The product channel**: AI capabilities embedded into the product, so customers generate deliverables directly inside the product — **knowledge work moves out of the internal organization and into the product**, scaling through compute rather than headcount.

The decisive evidence: the process channel cannot predict smaller organizations. AI startups are 2.6 times[1-29] more likely than non-AI peers to name ChatGPT/Copilot/Cursor in job postings — but that indicator cannot predict smaller teams. After controlling for the process channel, product-embedded AI remains significantly associated with fewer people and flatter structures.

The largest differences appear in service businesses: in service startups such as therapy, tutoring, and telemedicine, AI startups are about 70%[1-29] smaller than non-AI peers. Cases: Gamma (AI presentations; roughly 30 people reached $50 million in annual revenue within two years); FazeShift (an accounts-receivable AI agent; 10 people won dozens of enterprise clients, replacing the AR team at each client).

A cautious conclusion about the labor market: every AI-native company is smaller, but total employment need not fall — AI dramatically increases the number of startups (PitchBook's 2024 AI seed funding was about 8 times the 2020 average)[1-29]. Extrapolating from the firm level to the market level requires caution.

Limitations: the sample is YC/VC-backed startups, which may not generalize to mature large enterprises; the "AI-native" classification is the researchers' own definition; and the working paper has not been peer-reviewed.

3.2 The INSEAD/HBS Field Experiment: Rare Causal Evidence

The randomized controlled trial of 515 startups mentioned in the previous chapter (*Mapping AI into Production*, 2026)[1-33] is the scarcest kind of causal evidence in AI organization research: tools, skills, and budgets were fully equalized, and only the "organizational search space" was changed (the treatment group was shown how AI-native organizations restructure). The result: treatment-group use cases +44%, revenue 1.9x, external funding needs −39.5%.

The "mapping problem": what limits AI gains is not the cost of technology or skills, but the cognitive bottleneck of "discovering where and how AI creates value in your own production process."

Limitations: a 10-week short-term experiment; a startup sample; the 1.9x revenue figure is a short-term relative increment with small absolute values (on the order of, say, $40,000).

3.3 WEF's *AI-First Operating Models*: A Systematic Framework for Operations

The World Economic Forum's (2026) core proposition: **layering AI on top of operating models designed for the pre-AI world (linear processes, static roles, incremental optimization) is a structural failure.** Global AI investment exceeded $250 billion in 2024, yet in most organizations "AI has not fundamentally changed the way they operate."

Three shifts:

1. **Work and teams: from process management to human–AI collaboration** — early AI-first organizations already have **human-to-AI ratios exceeding 10:1** (1 human : 10+ AI); delegation is a management skill that requires training and certification (the You.com CEO: adoption in mature organizations only really took off after a training-and-certification program was launched);
2. **Workflows: from linear processes to dynamic AI systems** — the Rubrik CEO's implementation path: **"go business line by business line; in each line, find 3–5 workflows that are purely manual or SaaS-plus-human,**

and define end-to-end AI-driven outcomes"; the starting question determines everything (Lightspeed: "If we had unlimited intelligence, what would we build?");

3. **Metrics: from process optimization to dynamic value creation** — outcome-oriented, with reliability/accuracy/governance first to build trust.

Key judgment: **competitive advantage comes from orchestration, not experimentation.** Successful leaders treat capability, process, outcome, and business-model redesign as a single integrated evolution.

3.4 Tencent Research Institute's *AI-Native Work Report*: A Complete Framework from a Chinese Perspective

Tencent Research Institute (Chinese: 腾讯研究院) published a 40,000-character report in May 2026, with lead authors Si Xiao, Yuan Xiaohui, and Yu Yi (Chinese: 司晓、袁晓辉、余一). The most widely circulated part is its **competitiveness formula**:

> **Organizational competitiveness = talent density × AI leverage ÷ organizational friction**

If the numerator doubles but the denominator stays fixed, the net effect is discounted; **halving the denominator is equivalent to doubling the numerator** — reducing organizational friction (waiting/approvals/alignment/information decay) is usually easier to move than piling on talent.

The report defines four structural characteristics of the "Super-Individual" (all required):

1. **An AI-first workflow**: AI is the default starting point — "I let AI run first, then judge and correct on top of its output";
2. **An order-of-magnitude leap in capability boundaries**: 10x+ output; one person runs the full chain from idea to delivery;
3. **Extreme proactivity**: doesn't wait for organizational assignment; a natural boundary explorer;
4. **Influence spillover** (the key threshold for identifying Super-Individuals): **efficient individuals only make themselves faster; Super-Individuals make the team faster.**

It also outlines four emergence paths (bottom-up spontaneity / organizational selection and cultivation / atmosphere creation / founder-driven), three team forms (node-radiation / network collaboration / AI-hub), and one harsh judgment about the capability reshuffle: **AI is an accelerator of divergence, not an equalizer — only those who were already excellent become more excellent, and the gap widens.**

We must emphasize the report's sample bias (this is the knowledge base's systematic critique of the report): roughly 80% of its cases come from information-intensive, digital-native industries with fewer than 500 employees, with zero coverage of physical-world industries (manufacturing lines / medical clinical settings / logistics). The evidence in the report supports only this: **in information-intensive, small-team, digital-native industries, AI-native organizations can dramatically accelerate.** Before applying it to physical industries or large organizations, ask first: is this industry's bottleneck information processing, or the physical world?

3.5 Large-Sample Data from Authoritative Institutions

McKinsey, *State of AI 2025* (November 2025): 88% of organizations regularly use AI[1-03] in at least **one business function** (78% last year); but about two-thirds are still in the experiment/pilot stage and only about one-third have begun scaling; only 39% attribute any degree of EBIT impact to AI, and most of them say the contribution is under 5%; "AI high performers" (EBIT impact ≥5%) account for only about 6%[1-03]. **Many companies use AI; very few make money from it.**

BCG's *AI at Work* series: a clear leadership–frontline gap — more than three-quarters of leaders use GenAI multiple times a week, while frequent frontline use stalled at 51%[1-04] in 2025 before jumping to 74%[1-06] in 2026 (+23 percentage points). Half of companies are moving from "Deploy" to "Reshape" (redesigning workflows).

Microsoft's *Work Trend Index*: in 2024, 75% of knowledge workers already used AI[1-13]; in 2025 it introduced the "Frontier Firm" concept[1-14] (about 9.3% of surveyed leaders) — 71% of frontier-firm leaders say their company is "thriving," versus only 39% of employees globally; the most important finding of 2026: **organizational factors (culture, manager support, talent practices) contribute twice as much to AI impact as individual effort** (based on a permutation-importance analysis of 29 factors, $R^2 \approx 0.68$–0.69).

Stanford HAI's *AI Index 2025*: in 2024, 78% of organizations reported using AI[1-16] (55% in 2023).

IMF: AI will affect about 40% of jobs globally; roughly 60% in advanced economies, 40% in emerging markets, and 26%[1-20] in low-income countries — note that these are "exposure" estimates, not unemployment forecasts, and about half of exposed jobs may be augmented rather than replaced.

WEF's *Future of Jobs 2025*: by 2030, job disruption will equal 22% of current jobs: 170 million created, 92 million eliminated, a net gain of 78 million[1-27]; 77% of employers plan to upskill their workforce, and 41% plan to reduce headcount because of AI automation — expectations, not facts.

JetBrains' *2026 Developer Ecosystem Survey* (August 2026; 15,000+ professional developers): the adoption curve of AI coding agents is the hardest leading indicator on the engineering side — 90% of professional developers use AI coding agents weekly and 68% daily; Claude Code's workplace adoption rose from 18% in January to 39% (47% in the US), and 31% of developers use it as their only primary tool; GitHub Copilot fell from 29% to 21% and lost the top spot, while OpenAI Codex climbed from 3% to 16%[1-36]. Tool rankings change, but the pattern does not: the adoption curve always arrives first where output is most measurable and feedback loops are shortest — the order in which AI penetrates an organization is the order of value measurability.

UK Department for Business and Trade Copilot pilot (officially published): 1,000 licenses were rolled out over three months, producing an average of just 1.14 Copilot actions per user per day. PowerPoint decks came out 7 minutes faster (18 down to 11 minutes) but at half the quality score; Excel analysis was actually completed more slowly and at lower quality; email time savings were, in its own words, "extremely small." The official conclusion, verbatim: **"We did not find robust evidence to suggest that time savings are leading to improved productivity." And yet 72% of users said they were satisfied or very satisfied**[8-89] — satisfaction decoupled from output, the cleanest controlled demonstration that individual gains do not equal organizational gains.

Faros AI telemetry across 22,000 developers (2025): after AI adoption, individual throughput did rise, but in the same period median time in PR review increased by 441%, bugs per developer rose 54%, and incidents per PR rose 242% [8-90]. McKinsey's comparison is blunter: when developers do not adequately verify AI-

generated code, bug density in those projects runs 23% higher than in projects where human oversight is maintained[8-90]. **Output went up, system quality went down — teams watching only speed metrics never see it.**

NBER Working Paper w35559, "Replaceable but Employed" (Joshua Gans, 2026): automation can harm workers without displacing them. In the model, workers value both producing useful outcomes and the meaning that comes from the outcome depending on their own contribution; a credible machine substitute erodes the second source even if the firm keeps the worker. With fully adjusting wages the meaning loss is capitalized into compensation; with incomplete adjustment the worker bears part of it. And a "meaning externality" makes automation more likely, so profitable development can be socially harmful[1-37]. **The conclusion in one line: automation can reduce the value of work before it eliminates the job. iResearch (Chinese: 艾瑞咨询), *Enterprise AI Agent Adoption: From "Shallow Prosperity" to a Value Loop* (August 2026, via 36Kr)**: in Q1 2026, AI adoption among large and mid-sized Chinese enterprises reached 90.9%, with 81.3% adoption for next-generation AI — yet 67.3% of companies remain at L1 (exploratory/pilot), 24.0% at L2 (localized enablement), and only 9.1% have reached L3 (systematic optimization), with L4 and L5 at zero. Project composition is even more telling: general-assistance scenarios account for 83.7% of enterprise agent projects against just 16.3% for deep professional scenarios, and roughly 30-40% of enterprise agent projects may stall or be shut down within 18 months because the expected ROI never materializes[1-39]. The value of the dataset is that it splits "adoption" and "maturity" into two separate rulers: **adoption measures what the organization bought; maturity measures what the organization changed — for large Chinese enterprises in 2026 the former is near saturation while the latter is still under one in ten.**

3.6 A Warning on Data Use (This Book's Citation Discipline)

Putting all the numbers above together, there are five citation disciplines:

1. **Definitions come first**: the "95% failure rate" (MIT, zero organizational return), "30% abandoned" (Gartner, after PoC), and "88% adoption" (McKinsey, at least one function) are not contradictory — they are three different denominators;

2. **Report conclusions vs. media retelling**: media retelling often distorts (e.g., Fortune reported the MIT report's sample as 150 interviews/350 questionnaires, while the report actually covered 52 organizations/153 executives)[1-02]; this book always follows the original report;
3. **Forecasts vs. facts**: most of the Gartner/Forrester/WEF numbers are forward-looking forecasts or employer expectations, not events that have already happened;
4. **Sample bias**: McKinsey/WTI/BCG skew toward white-collar workers, large enterprises, and self-selected survey participants; every "global" claim must be checked against the original sampling scope;
5. **Conflicts of interest**: Microsoft, BCG, and McKinsey all sell AI products/consulting to enterprises — keep their positions in mind when citing their conclusions.

3.7 Bounded Autonomy and Occupation-Level Exposure: Two Cross-Cutting Studies

The previous sections cover evidence at the company and operations level. Two cross-cutting studies published in the second half of 2026 fill in two cells that had been empty: one answers "what actually runs in production," the other "who is actually affected."

The first is a retrospective on 150 production-grade agents. The Brief Script team collected 392 public records and froze 150 qualifying deployments across 119 organizations (evidence cutoff 2026-09-02), then classified them by degree of autonomy. The central finding is that *bounded* autonomy, not full autonomy, is the center of gravity: 57/150 (38.0%) are autonomous actors with explicit boundaries, rising to 49.3% when the tier above is included; among the samples with the strongest evidence, 91.2% report quantified outcomes, 94.7% clear a "moderate or strong" evidence threshold, and the average evidence score is 76.6/100[1-40]. The other side matters just as much: first-order ROI mostly stays at the operational level — 71 cases report time or cycle effects and 50 report productivity or throughput, while only 22 disclose cost or financial impact and 10 disclose revenue; software-engineering deployments are unusually measurable (13 cases, all reporting quantified outcomes, 69.2% at high-autonomy tiers), whereas payments and treasury deployments are technically real but economically under-measured (19 cases, only 15.8% reporting

quantified results). In other words, **the industry is currently best at proving that time was saved and worst at proving what the saved time is worth** — the mirror image of this book's recurring point in Chapter 5 that efficiency gains are not delivery gains.

The second study breaks "AI impact" down from industry to occupation. Research from the Washington Center for Equitable Growth (C. Combemale et al.) shows wide variation in generative-AI exposure across occupations within US logistics: cognitive-routine roles are the most exposed, while jobs requiring physical work and situational judgment are far less exposed[1-41]. The direct implication is that industry-level claims such as "logistics will be hit by AI" do not survive at the occupation level — what actually needs re-laying-out are desk-based functions such as dispatch, documentation, billing and customer service. Organizationally, the transformation cost lands first on two very different groups inside the same company: one group's job definitions have to be rewritten, the other's way of collaborating has to change alongside automated equipment and intelligent scheduling. This is the same mechanism seen from two angles as the skills gap in Chapter 6 and the "where do industries get stuck" analysis in Chapter 10.

3.8 What Actually Runs in Production: Automation Under Constraint

Section 3.7 used a public-record audit; this section adds a second measurement basis — practitioner self-report plus in-depth enterprise cases.

UC Berkeley's *Measuring Agents in Production* takes a full reading of agents in production. It covers 306 practitioners, 20 enterprise deployments and 26 industries. The motives are thoroughly practical: 73% name "increase productivity" as the primary goal, 63.6% want to cut manual hours and 50% want to automate routine labor; benefits that are hard to quantify rank far behind — risk avoidance at 12.1% and faster incident response at 18.2%. By industry, financial services and banking lead at 39.1%, followed by technology (24.6%) and enterprise services (23.2%)[1-42].

Almost all of these systems play assistant to a person, not decision-maker for a system. 92.5% of agents serve human users directly, 52.2% of them internal employees; only 7.5% serve other software systems, so fully automatic agent-to-agent interaction remains distant. Latency is not the binding constraint either: 66% of systems tolerate minute-level or longer response times — against the hours or days

a human needs for the same task, minutes are still an order-of-magnitude gain, so teams spend their effort on output quality and reliability rather than sacrificing capability for low latency.

The engineering choices at production grade are far more conservative than the academic narrative. Among the 20 deep cases, 85% use closed-source models; 70% do no weight fine-tuning at all, 78% build prompts manually (or with AI assistance), and 12% of prompts exceed 10,000 tokens; in the survey 60% said they were willing to use third-party frameworks, yet 85% of actual teams built their own and called model APIs directly, citing full control and less dependency bloat. Autonomy is strictly step-limited: 68% of systems run no more than 10 steps before human intervention, 47% fewer than 5; 80% use a predefined static workflow in which the agent may decide inside the process but cannot invent new steps. Evaluation is equally plain: 75% of teams use no public benchmarks at all because their business is too specific, and the rest build their own sets; 74.2% rely on human-in-the-loop validation, and 51.6% use an LLM as judge but all of them add human spot checks. The top challenge is reliability (37.9%), far ahead of compliance (17.2%) and governance (3.4%)[1-42].

Together the two bodies of evidence falsify the "fully autonomous agent" narrative twice over. What runs in production is automation constrained on four sides: environment, step count, permissions and a human signature. The reliability problem is not solved by a stronger model but by shrinking the radius within which the agent can err. Organizationally, that shifts the point of capability building away from "pick the strongest model" toward four replicable constraint designs: separating write operations from read operations, sandboxing first, inserting an abstraction layer between the agent and production tools that exposes only the necessary capabilities, and governing the boundaries of inherited access rights.

3.9 The Core Judgment of This Chapter

The evidence chain is complete: HBS shows AI-native companies are **smaller, flatter, and higher-output per capita**[1-29] (driven by the product channel, not the process channel); INSEAD/HBS shows that **organizational knowledge itself produces causal revenue differences**[1-33]; WEF shows that **operating models must be redesigned around AI**; Tencent shows that **competitiveness comes**

from talent density × AI leverage ÷ organizational friction; McKinsey/BCG/ Microsoft show that **a huge gap exists between tool adoption and organizational returns**.

The evidence points exactly where Chapter 1 concluded: models are no longer scarce — what's scarce is organizations redesigned around AI. In the next chapter, we look at what the inside of such an organization looks like.

Chapter 4: Rebuilding Organizational Structure — From Hierarchy to Network

4.1 The Legacy Organization's Deadlock

Linear division of labor has exposed a fundamental contradiction under AI acceleration:

The old way	The new contradiction
Managing people by role	The people who can actually get things done span multiple roles
Breaking work down by process	AI completes in a day what used to take a week of milestones
Accepting deliverables at checkpoints	Deliverables themselves become "intermediate artifacts"; only the final outcome is value
Reporting and evaluation by rank	Those who take on fused roles don't receive the corresponding authority and rewards

> When one person can use AI to leap over steps that previously had to be handed off, and produce something closer to the final outcome, the legacy organizational framework becomes a constraint.

The core proposition of restructuring organizational form is: **use AI to replace the coordination and information-routing functions that hierarchy used to perform, so that humans can focus on judgment and creation.**

4.2 MarsWave: Five Practices of a Small Team Building from Zero

A small company called MarsWave (Chinese: 火星电波), which pivoted from ListenHub, completed its AI-native transformation in five weeks. Its five practices are the most concrete Chinese sample of "what an AI-native organization looks like":

1. Vibe coding shocks the organization. The CTO used Claude Code to build version 0.1 alone overnight — ideas could be presented directly. Before: product requirements → PRD → review → development → testing → release (weeks). Now: say it to AI → see the result → iterate (hours). Alignment shifted from "long documents" to "seeing the prototype directly."

2. The OPC model (human–machine–macro decision). Humans handle judgment (what to do, why, whether it's good), AI writes 99% of the code (how to write, how to implement), and managers make macro decisions (direction, resources, cadence). **Humans don't manage processes or schedules; they manage judgment, quality, and review.**

3. The birth of the Soul Team. The first core role that was neither engineer nor product manager — responsible for the product's **personality and emotional output**; its lead has a media background and can't code. Insight: once AI can handle "feature implementation," humans' differentiating value shifts to the "human-like" parts — empathy, personality, warmth.

4. A tool revolution. Linear, Notion, and kanban boards were abandoned; all code moved into a unified repository with no permission barriers. The repository "isn't for humans to read — it's for AI to read as context." The CEO's ideas go directly to AI, are automatically organized into Markdown, and become development context. **Essence: AI becomes the intermediary of information transmission, instead of layer-by-layer transmission between people.**

5. A new rhythm of front-load thinking and back-load review. In the first few days of each month the whole team stops writing code to align on plans; at month's end they re-review the code, cutting and refactoring. "Faster isn't necessarily better" — rhythm matters more than speed.

The failed experiment matters just as much: before the formal transformation, there was the "Task Tavern" (a task bulletin board where anyone could pick up any task) — a programmer's two-day new feature reached 80,000 users on launch day, but under business pressure the strongest people were pulled back to old tasks, and it ultimately failed. Lesson: **process improvement (patching the old framework) isn't enough — you have to design from scratch.**

4.3 Shmool: A CEO's Firsthand Subtraction in a Mature Organization

Unlike MarsWave (building from zero), Itay Shmool's case is about **subtraction within an existing organization** — dismantling the traditional hierarchy (VP → Director → Manager → Team Lead) into a single-layer AI-native organization. Core numbers:

Metric	Before	After
Decision latency	Days to weeks	Hours
Information fidelity	~60% (decays with each transfer)	~95% (direct transfer)
Builder-to-manager ratio	3:1	8:1+
Meeting overhead	~30% of work week	~10% of work week

Three key insights:

1. **The truth about middle management**: many middle managers are not "redundant layers" — they are excellent builders themselves, just pulled into coordination work by the old structure. Give them the chance to build again and they thrive. **Distinguish the management function from the managers themselves — the function can be automated, but people should not be simply removed.**
2. **Guild Masters replace management**: once management layers are removed, a new mechanism is needed to maintain professional standards. Guild Masters are **expert roles** (not management roles) who sit within teams and set standards across teams — they create no new reporting lines and are "the quality immune system of a flat organization."
3. **The AI platform is a precondition**: flattening without AI infrastructure equals chaos, not lean. Five core capabilities: self-healing systems, an AI creative engine, a unified experimentation platform, automated code review, and operations AI agents. **"The AI platform is what replaces coordination — this is non-negotiable."**

The human side of the transformation matters just as much: "Behind every box in the architecture is a person with a mortgage, a family, and a career. **How you treat the people who leave defines your culture more than how you treat the people who stay.**"

4.4 Block: Replacing Hierarchy with a World Model

Block, the payments company (Jack Dorsey), offers the large-company version of the framework: **use AI to replace the coordination functions hierarchy performed, and build the company as an agent.**

Block's four-layer architecture:

```
┌──────────────────────────────────────────────┐
│   Interfaces (Square / Cash App, etc.)   │  ← delivery surface
├──────────────────────────────────────────────┤
│            Intelligence Layer            │  ← proactively composes and pushes solutions
├──────────────────────────────────────────────┤
│               World Model                │  ← continuous machine-readable view of company + customers
├──────────────────────────────────────────────┤
│               Capabilities               │  ← atomic financial components, no UI
└──────────────────────────────────────────────┘
```

The revolutionary shift in the Intelligence Layer: from "product managers plan features" → the Intelligence Layer identifies timing and composes solutions; failure signals automatically become the roadmap; **product planning shifts from guess-driven to signal-driven.**

Three new human roles: Individual Contributors (ICs, given context by the World Model, making autonomous decisions), DRIs (Directly Responsible Individuals, short-term ownership of cross-domain problems, replacing project managers/product managers), and Player-Coaches (both building and developing people, replacing traditional managers).

> The World Model handles alignment; DRIs handle strategy and priorities; Player-Coaches handle craft and people development.

A critique that must be heard (a critical analysis of the Block framework): Dorsey's premise is that "the main value of humans is information routing," but if humans are also generating, interpreting, and creating signals, then subtracting humans means subtracting intelligence itself; the real bottleneck is not routing speed but **perspective loss** (signals die before they reach decision points). Core warning: **"Speed is not intelligence. Speed without integration is just faster blindness."**

4.5 Yang Renbin: The Organizational Brain and the AI Chief of Staff

In a 2026 interview with LatePost (Chinese: 晚点), Yang Renbin (Chinese: 杨仁斌), founder of Jingzhunxue (Chinese: 精准学) — an AI education brand founded by Yang Renbin — supplied the piece all previous perspectives were missing: **how the highest cognition and decision-making capability can be systematically injected into every frontline execution step.**

- **First principles of the organization**: solving three traditional deadlocks — the top-down decay of "highest cognition → frontline," the bottom-up distortion of "frontline facts → top," and the bandwidth bottleneck at the top;
- **Three steps**: ① model the decision layer's judgment methods into a callable "AI Chief of Staff / Organizational Brain" (initially injecting 300,000 characters of methodology) → ② inject it into every business site through context engineering (a decision-model index system) → ③ frontline real problems/disagreements/anomalies flow back, closing the loop to iterate the highest cognition;
- **AI coding is only 0% and 100%**: a hard rule that engineers are not allowed to modify code themselves — humans only give feedback and transform into "context engineers," going further than MarsWave's "AI writes 99% of the code";
- **Anti-document, anti-group-chat business discussion**: documents are negative assets (author bias plus information loss); preserve the original records of discussions, disagreements, and failures; deep discussions continue in AI conversations; offline voice must be transcribed to text and enter the context;
- **Context is Everything**: once model capability is replicable, what is truly scarce is context engineering;

- **Cultural premise**: "explain the Why thoroughly, and give enough AI (爱, 'love,' pronounced ài, is a pun on AI)"; an open culture — hiding problems is shameful, exposing them means solving them sooner; don't hold people accountable for making mistakes, hold them accountable for hiding problems or failing to update their judgment.

4.6 An International Comparison: The Changing Role of the Engineer

Anthropic's internal practice confirms the direction of role reconstruction: the engineer's role shifts from "writing code" to "**architect + referee**" — AI-powered automated code review is embedded in CI/CD, and post-hoc analysis shows it intercepted about one-third of the production bugs in claude.ai's history that caused downtime[7-28]; one engineer used AI to auto-fix 800+ API errors that humans estimated would take four years. At OpenAI, Codex became the primary work tool of every department (including non-technical ones such as legal, finance, and recruiting), accounting for 99.8% of the company's weekly output tokens[7-38].

4.7 Three Paths: There Is No Single AI-Native Organization

Putting this chapter's cases together with the international ones, there are three parallel paths to the AI-native organization:

1. **The shrink path** (Klarna): hiring freeze + natural attrition, headcount −38% [7-01], with AI replacing the headcount growth that demand would have required;
2. **The expansion path** (OpenAI/Anthropic): headcount and revenue grow together; AI-native is a growth engine, not a downsizing tool;
3. **The steady-state leverage path** (Shopify/Duolingo/Airbnb): full-time headcount flat or slightly up, with AI raising per-capita output.

There is no single answer for organizational structure, but organizational principles converge: AI handles information routing and execution; humans handle judgment, quality, and review; hierarchy grows thinner as coordination functions are replaced by AI platforms; experience shifts from a personal asset into an organizational asset. In the next chapter, we look at how workflows and decisions are concretely redesigned.

4.8 Task-Based Teaming and the Rise of Roles: When the Unit of Configuration Shifts from the Job to "Human + Agent"

In September 2026, Chen Chunhua (Chinese: 陈春花) laid out a set of interlocking organizational judgments in an interview[8-97]. She defines an AI-native organization as one in which AI participates in sensing, deciding, and executing, and where people and agents form a stable collaborative relationship. At the job level, her formulation is that **"jobs may fade while roles rise"**: in an era when tasks change quickly, one person takes on multiple roles per project and learns to invoke different agents. She calls people who work with multiple agents "super-individuals," and tasks that once required a whole department may in future be carried by much smaller teams. The resulting structure she calls a "galaxy structure": people assemble around a task, disband when it is done, and reassemble around the next one. Much of the information relay and process coordination that middle managers once handled will shrink, while business understanding, resource mobilization, and cross-functional collaboration become more valuable — and the experience middle managers accumulated is precisely the most important knowledge source for training agents. That raises a new incentive question: once employees hand their experience to the system, how does the company recognize that contribution? She argues that incentives must measure both performance contribution and knowledge contribution, otherwise knowledge capture degenerates into a one-off administrative chore.

The engineering community arrived at the same conclusion in engineering terms. A CCF (China Computer Federation) technology forum put it bluntly: **in the AI-native era, the smallest unit of an organization is neither a job nor an individual, but the "human + agent" combination**; and system design should take precedence over model capability — "a good system can get 90-point work out of a 70-point model, without errors"[8-98]. The discussion splits organizational evolution into three stages — tooling, agentification, and an organizational operating system — with the third stage closing the full loop of strategy, execution, and review. One operator corroborated it with his own case: the business grew fivefold and its geographic coverage expanded from 12 cities to more than 40, while headcount fell from 4,200 to 2,800.

Two distinct forms of the new configuration unit are already visible in practice. CITIC Securities (Chinese: 中信证券) describes it as "one digital employee per role, one assistant per person" — configuring agents **by job** rather than by scenario, which

means agents are written into job design rather than listed as projects[7-81]. Kavak, the Latin American used-car platform, went a step further: **it generates a dedicated agent for every customer, rather than one agent per job or task**, on the reasoning that an agent is essentially a "context isolation container"[7-80]. Both forms point to the same organizational conclusion: as the unit of AI configuration sinks from "process" to "job" and then to "individual," what must be redrawn is not the reporting line but **how tasks are divided, who holds the context, and who signs for the result.**

4.9 Collapsing Jobs: From Skill Division to the "Minimum Collaboration Unit"

Now that AI has lowered the barrier to learning across disciplines, a more radical question follows: do we still need so many skill-divided jobs at all? Alibaba Cloud CIO Jiang Linquan's (Chinese: 蒋林泉) answer is to merge adjacent jobs until they can merge no further. His judgment is pointed: "In the face of this productivity [AI], the old, skill-centered proliferation of jobs is inherently out of place" — any business flow must cross so many jobs that people are forced into coordination, alignment, and meetings, and the efficiency share of any single node is small, so "even if an individual improves tenfold, end-to-end efficiency may not rise"[8-117]. He puts a hard number on where the bottleneck sits: the rate at which humans exchange information is "only 7 bits per second" — if the number of nodes has not dropped, AI can be as fast as it likes and it will not help.

The form this takes is "Half-Stack": not the full-stack engineer ("being broad and deep does not fit the human brain; full-stack is almost an outlier"), but merging adjacent skill jobs — product manager, design, and front-end combine into PDFE; architecture and back-end combine into ABE; the two connect through an API contract[8-117]. The effect shows up immediately in the requirements chain: previously a PRD had to be aligned sequentially with design, front-end, and back-end, at least two weeks per round; now PDFE confirms directly with the business using a live demo, in half a day. Fewer participating roles and people compresses coordination cost while actually raising context density — only then does local efficiency gain a chance to become end-to-end efficiency.

What accompanies this is a wholesale change of measurement. Jiang Linquan excludes the industry-favored "AI code-generation rate" from assessment entirely — "the AI code-generation rate is a process metric, and once an organization observes such a process metric, AI very easily becomes toxic"; coding is only about 20% of the software engineering lifecycle, with the bulk in alignment, review, communication, and rework, so measuring overall effectiveness by its most replaceable step is a mistake. What he actually watches are effective lines of code per person and defects per thousand lines: over a year, front-end effective code per person rose to 3x and back-end to 2x, while defects per thousand lines fell 30% (front-end) and 55% (back-end) — with not one person added[8-117]. The same team used AI to lift test coverage from 20% to a weighted near-100%, turning "shift left" from correct-but-expensive into an executable engineering practice.

This practice leaves two propositions organizational design can pick up directly. First, when AI lowers the cost of learning across domains, **reducing the number of jobs is itself a source of efficiency** — what shrinks is the coordination chain, not headcount; the precondition is writing the interface contract (here, the API) clearly, otherwise the merge merely moves friction from between departments onto one person's desk. Second, job consolidation demands a new measurement system: assessing an organization by its most easily quantified process metrics (code-generation rate, token consumption) pushes people to apply AI to the most replaceable steps while leaving the real bottleneck in place. Jiang Linquan's own phrase is "skill inflation, taste deflation": AI makes front-end, design, and testing skills readily available, and what becomes scarce is judgment about business value and quality — "AI can only reach average; people with taste can define what good is"[8-117].

Chapter 5: Redesigning Workflows and Decisions

5.1 Redesign First, Automate Second

In 1990, Michael Hammer published a famous article in the *Harvard Business Review* titled "Don't Automate, Obliterate." His core point is even more applicable in the AI era: **before automating a bad process, ask why that process exists in the first place.**

The first principle of AI-native workflow redesign is: **not "give everyone a chatbot," but redesign how work flows, how decisions get made, how data is captured, how humans review risk, and what AI is allowed to assist with or act on.**

The fundamental difference between an automation-first organization and an AI-native organization:

Question	Automation-first organization	AI-native organization
Starting point	Where can we add AI?	**What work should change?**
Success metric	How many tasks were automated / how many prompts were used	Whether the outcomes of the whole workflow improved
Main risk	Faster rework	Discovering redesign gaps before scaling
Data approach	Use existing data	Redesign data capture around decisions
Human role	Post-hoc reviewer	Responsible designer, supervisor, and owner of exceptions
Scaling pattern	More tools and pilots	A repeatable workflow-redesign loop

5.2 Nine Key Workflow Redesigns

1. Start from business outcomes, not AI tools. Outcomes must be specific enough to guide trade-offs: "30% fewer supplier-invoice exceptions without adding approval risk" beats "use AI in finance." Technology choices follow workflow intent.

2. Map the real workflow before automating the official one. The official process diagram and how employees actually work (inbox shortcuts / private spreadsheets / informal escalation paths / exception handling) exist side by side as two versions. Delete steps before automating: merge duplicate approvals, turn low-value checks into rules, give exceptions an owner. **Don't teach AI to preserve unnecessary work.**

3. Redesign intake so AI gets better input. Many AI projects die at the door: expecting AI to classify, route, or decide on messy input that was never designed for it. Required fields, structured options, validation at capture points, automatic enrichment from trusted systems, and flagging low-confidence cases. **Don't blame the model for weak input before redesigning the front door.**

4. Separate rules / automation / AI assistance / agents / humans. Not every step needs AI: stable rules → rule automation; system handoffs → workflow automation; language-intensive review → AI assistance; pattern recognition → AI models; low-risk multi-step tasks → constrained agents; high-accountability decisions → human plus AI support. Prevent two errors: using AI where rules suffice, and delegating high-risk decisions just because AI can generate confident-sounding suggestions.

5. Build a workflow data foundation, not an abstract data lake. Ask "have we captured the data needed to make the workflow better?" rather than "do we have data?" Record when humans override AI suggestions and why — the best learning comes from the redesigned workflow itself.

6. Define decision rights before AI systems act. If humans aren't clear on decision rights, AI is even less safe. The decision rights table is the tool that operationalizes this:

Scenario	What AI may do	What humans retain
Classification / routing	AI acts on high confidence	Humans review low-confidence cases

Scenario	What AI may do	What humans retain
Drafting	AI recommends drafts	Humans approve sensitive content; template and tone control
Low-value refunds	AI acts within limits	Humans review over-limit cases; thresholds + logs + fraud checks
Contract changes	AI assists only	Humans decide
Risk escalation	AI acts immediately	Humans investigate and close

7. Replace manual handoffs with event-driven work and review queues. Stop treating people as glue between systems. Trigger → create record → enrich → apply rules → AI classify/summarize → route → exceptions enter a visible review queue (with context/priority/owner/deadline/escalation path). Don't make handoffs invisible; make important handoffs observable.

8. Measure the whole workflow, not AI tasks. Task-level time savings mislead (drafting got faster but review got slower; classification got faster but the queue got wrong). Metrics: cycle time, first-time-right rate, exception rate and exception age, review time, satisfaction, cost per completed case, rework rate, AI confidence and coverage, escalation quality, incidents/control violations. **After the pilot, ask: did the work improve, or did AI just make one step look faster?**

9. Create a repeatable 90-day workflow-redesign cadence.

Processes themselves can be redesigned: a review system is not the same thing as a PR. Amp, a 20-person team, pushes straight to main without pull requests and still passes SOC 2[8-64] — auditors never cared about the git workflow; they care that changes are authorized, tested, approved, and recorded. Their control stack: push permissions restricted by business function, signed commits (GitHub verified), fully automated CI validation, and an audit trail linking commits to business context. The scaling insight: risk is not uniform inside an enterprise, and calibrating every system to "the scariest one" is hidden waste — first ask "what risk is the PR actually managing," then decide where it is needed.

Break the process into three buckets instead of adding AI to every step. Varick (which deploys agents for enterprises with more than $500 million in revenue) sorts every redesigned step into one of three categories[8-89]: **deterministic** (if X then Y, no judgment — plain code: cheap, auditable, immune to hallucination, and fast);

agentic (thousands of past examples of human judgment with recorded outcomes, at low enough risk, such as deal-desk approvals or GL coding — use the model for judgment, especially when the output is yes/no, route-to-this-team, or flag/don't-flag); and **human-in-the-loop** (too risky or too little history — assemble the evidence for a person so they can decide in 30 seconds instead of spending 40 minutes digging through email). On that basis they compressed a global company's monthly reconciliation of more than 300 bank accounts from 25 steps to 3 agents plus 2 human checkpoints. **The money is not in making each step faster; it is in deleting the queues and handoffs** — Hammer's 1990 example remains the best footnote: an insurance application sat in process for 22 days while actual working time was 17 minutes, so doubling the speed of those 17 minutes saves eight and a half[8-89]. The results across their client deployments: month-end close cut from 18–22 days to 7–9, AP exception handling down from 600–800 invoices a month to under 50, and payroll corrections down 90%[8-89].

Four engineering disciplines that cannot be reordered. AI-native engineering practice compresses into one sequence[8-90]: make **specifications executable** (tickets spell out acceptance criteria, constraints, dependencies, and failure cases — the bar being that hand it to a new engineer or an agent, and both produce a roughly similar first plan without a clarification call); treat **context as an asset** (architecture notes, coding standards, known edge cases, and acceptable patterns live where the work happens, not in a Slack thread); **build verification before expanding autonomy** (deterministic tests, static analysis, policy checks on sensitive changes, and bounded tool permissions with audit trails all come before broader automation — this is earning the right to accelerate); and make **review the center of leverage** (once generation is cheap, what is scarce is judging correctness, architectural fit, and long-term maintainability, so experienced engineers should concentrate there rather than rewriting by hand). The rollout is staged: weeks 1–4 cover specifications, context, and verification; weeks 5–12 add review, continuous QA, and standard delivery paths; only from the second quarter onward do end-to-end ownership, system-quality metrics, feedback loops, and engineer capability building.

5.3 The 90-Day Redesign Cadence (The Actionable Core)

- **Days 1–15: Select** — a process with visible pain + measurable value + sufficient volume + controllable risk;

- **Days 16–30: Map** — the real workflow / systems / data / decisions / handoffs / approvals / exceptions / owners / current performance;
- **Days 31–45: Redesign** — delete steps, clarify ownership, define decision rights, standardize intake, improve data capture, assign people / rules / automation / AI / agents to each step;
- **Days 46–60: Build** — workflow / integrations / prompts / access control / review queues / dashboards / logs / training;
- **Days 61–75: Pilot** — real users run real cases inside safe boundaries, measuring the whole workflow;
- **Days 76–90: Govern and scale** — kill / fix / scale, record the lessons, pick the next process.

5.4 Eight Common Mistakes

① Treating AI access as transformation; ② automating before simplifying (AI accelerates work of the wrong shape); ③ using AI where rules suffice; ④ ignoring exception work (the real value lies in handling messy cases); ⑤ measuring prompts instead of outcomes; ⑥ excluding employees from the redesign; ⑦ giving agents power without control (requires thresholds / logs / permissions / review queues / rollback / named owners); ⑧ redesigning the whole company at once (start with one process).

5.5 Dividing Labor Between Humans and AI: From "Full Replacement" to "Three-Layer Routing"

Beyond workflow redesign, designing the boundary of human–AI division of labor is the core of decision redesign.

Anthropic's internal evidence gives a key number: most employees believe that only 0–20% of work can be "fully delegated" to AI[8-40]. In other words, the human–AI division of labor in an AI-native organization is "supervised collaboration," not "hands-off automation." The number of autonomous actions Claude Code could take before human intervention was needed grew from about 10 to about 20 — this "intervention threshold" is dynamic and moves as model capability improves.

The hybrid-model **three-layer routing** that Klarna distilled from its customer-service reversal is currently the most mature template for dividing labor:

- **Layer 1: AI handles routine volume end to end** (targeting 60–70% of traffic) — order status, basic returns, FAQs;
- **Layer 2: AI-assisted human** (AI drafts, human reviews and sends, 20–25%);
- **Layer 3: Human-led high-value / escalation scenarios** (5–15% of traffic, but the greatest retention impact) — complex billing disputes, fraud, account cancellation.

Lesson: Klarna's first round of AI customer service only did Layer 1 (and did it aggressively); overall volume-based metrics (resolution rate, first-response time) looked good, but CSAT for complex interactions dropped significantly[7-14] and the repeat-contact rate rose — the overall average masked a quality collapse in retention-critical scenarios. **You must track satisfaction for "complex/escalation interactions" separately.**

Treating AI as a compiler leads to frustration; treating it as a collaborator works. One engineer's observation is worth remembering: code gives certainty (same input, same output; a difference is a bug), humans give uncertainty (a colleague may understand intent and produce a better result), and AI sits between the two — rather than treating it as a compiler that precisely executes instructions, collaborate with it the way you would lead: share context, explain the desired outcome, set boundaries, respond to feedback. The core shift is investing in **expressing intent** — explaining why the work matters, what a good result looks like, and where judgment is needed. "The technology is new; leadership is not." This is also the underlying capability for the "human–AI division of labor design" in Chapter 8.

There is also an underappreciated ordering problem on the cost side: **choose the router first, then the model.** Most teams building agents pick the model first and the architecture second — backwards. Model choice should be the last decision, not the first. What actually determines cost and quality is the router: a small piece of code that decides which tier of model handles each request. Routing has three layers: a **skill classifier** turns the raw request into a concrete operation (intent recognition), the **router** decides which tier executes it (reading only the classification label plus a few features: complexity, context size, historical success rate), and a **model selector** picks the cheapest model within the tier that clears a confidence threshold. The classifier is a language problem; the router is a scheduling problem — conflating them

buries model choice inside the prompt and kills the ability to A/B different models on the same operation. Get routing right and 70–80% of traffic can run on local models or async models; Coinbase used "better defaults, routing, and caching" to halve AI spend[8-80] while token usage grew exponentially. Ask one question first: how much work actually needs a real-time answer? Once you can queue work, the answer is often: very little.

Why the human–AI division of labor must be computed end to end. ByteByteGo's interview with Meta's ads-systems architect supplies a denominator that is easy to get wrong: **only 20–30% of an engineer's time goes into writing code**, while review, testing, coordination, and governance consume the other 70–80% — and that is exactly where the bottlenecks form. After that team systematically removed the surrounding bottlenecks, it achieved a 1.8–2.4x delivery speedup over six months[7-75]. Their division-of-labor pattern is "humans set direction, AI executes, humans review results": people set the plan and success criteria, AI implements and self-verifies, iterates on its own until the criteria are met, and humans approve the final output — yielding a 40–50% speedup over the previous development loop for one large team, while another team reached human-on-the-loop in under four months, against the 6–12 months such transitions usually take[7-75]. This also corrects the figure at the start of 5.5: the share of work that can be fully delegated to AI remains low, but **what actually determines organizational returns is whether the other 70% beyond generation gets redesigned too.**

5.6 Corroboration with Chinese Practice

The three common features from Chapter 2 (AI-informed decisions replacing experience-based decisions, unifying business flow and workflow, making expertise reproducible) all have concrete implementation mechanisms in this chapter:

- **AI-informed decisions**: Huawei (Chinese: 华为) makes intelligent analytics a default capability of its data platform — "you don't go query it; the system gives it to you automatically";
- **Unifying business flow and workflow**: Feishu (Chinese: 飞书; Lark internationally) connects IM, documents, and business flows, with AI intervening in project nodes in real time;

- **Making expertise reproducible**: Transn's (Chinese: 传神) AI automatically records decision logic and updates business rules, turning personal experience into organizational assets — at the same time, Yang Renbin's "decision model index" from Chapter 4 (modeling the decision layer's judgment methods as a callable system) and the decision rights table are two sides of the same coin: one is the governance side, the other the cognition side.
- **Governing AI coding**: Meituan (Chinese: 美团) reapplied its "eval agent" methodology to managing AI coding — first "human–human alignment" (one dictator beats ten democrats), then "human–AI alignment" (constraints written as AI Rules, with a human–AI agreement rate held at 90% or above; reverse the order and the AI Rules become empty words). AI code review uses higher-tier models to review lower-tier output, cross-vendor mutual review, plus a Pre-PR mechanism; technical debt is dissolved as "ride-along work" attached to business requirements, with zero dedicated scheduling. This system keeps a codebase of 310,000 lines — about 90% AI-generated — maintainable[8-83]. It also rewrites the definition of experience value: from "being able to see everything" to "knowing what matters." **A code-generation rate above 30%, with essentially unchanged delivery efficiency — Kuaishou turned that gap into a three-year retrospective.** In 2026 Kuaishou's R&D efficiency committee published the AI research-and-development paradigm shift of its 10,000-person engineering organization: from 2023 to 2024 it first pushed platformization, digitization, and lean operations until tool penetration exceeded 95% and process automation 94%, lifting per-capita requirement throughput by 41.57%; during "Intelligence 1.0" (June 2024 to June 2025) it focused on individual developer productivity, reaching an AI code-generation rate above 30% — while organization-level delivery efficiency stayed "essentially flat"; since July 2025 it has moved to "Intelligence 2.0," retargeting the effort from individual speed to organization-wide throughput along an explicit ladder of L1 AI assistance (Copilot) → L2 AI collaboration (Agent) → L3 AI autonomy (Agentic) [7-77]. The takeaway is a formula any organization can copy: **using AI coding tools ≠ individual productivity gains ≠ organizational productivity gains** — for individual gains to propagate, you first have to know which step is the bottleneck (Kuaishou built an efficiency model specifically to locate it), otherwise you just pile output in front of the slowest workstation.

Faster coding is not faster delivery. A widely cited engineering analysis puts it concretely: in the morning AI generates eight features at once; in the afternoon eight pull requests wait for review and the test environment queues up; three days later the business is still confirming requirements, security has just started checking permissions, and operations says this week's release window has closed. Management sees "a week of code generated in a day"; the business sees requirements that are no less late, with more rework and coordination. OpenAI's 2026 agent-first software engineering experiment — a team starting from an empty repository, using Codex to generate application logic, tests, CI, documentation and observability code, estimated at roughly one tenth of the time of handwritten code for one internal product — is often summarized as "shipping 10x faster," but the original stresses that engineers shift to designing environments, expressing intent, and building feedback loops[7-79]. A second piece of evidence comes from benchmarking: change the harness for the same model — the software system that manages its tools, context and task execution — and task success rates move within ±2% on SWE-bench Lite and about ±5% on Terminal-Bench 2.0, while cost varies by 2-5x; Claude Code costs about 2.0x the minimal open-source harness Pi on SWE-bench Lite, with an initial context more than 10x larger. **Changing the harness before changing the model is often cheaper than upgrading the model; and the delivery bottleneck is always the slowest step, never coding.**[7-78]

Half a year later, engineers at two more companies spelled out the same path in more detail. A roundtable between the R&D leads of Kuaishou (Chinese: 快手) and Xiaohongshu (Chinese: 小红书) quantified the contradiction in a single set of numbers: AI's code contribution had reached 60% and engineers felt roughly 40% faster, yet requirements-delivery efficiency and organizational R&D throughput did not rise in step[8-121]. The attribution fell in three places — the organization still used the traditional R&D division of labor, information kept leaking as it passed among roles, and business/domain/engineering knowledge had not been consolidated and connected; in other words, the bottleneck was not the tool but collaboration and the knowledge system. The paths they describe match: Kuaishou's fix is to clarify tasks proactively and define an SDD plan up front, and downstream to visualize code changes and run cross-agent review, using SubAgents to relieve the context-window limit, moving gradually from Human in the Loop to Human on the Loop; Xiaohongshu built its own context framework and agentic system, folding expert experience into model control to balance generalization against output quality. A counterintuitive

observation is that **small and mid-sized teams land it faster** — they can adopt ready-made community solutions (Claude Code + a harness), cheap and quick to fit, and only need to watch effect metrics such as alignment rounds and adoption rate; large organizations must split into small teams and standardize step by step. The roundtable also gives a measurement tip: during rollout watch penetration and AI-code share; after it spreads, watch requirements throughput per person and delivered value, and observe by requirement tier (L1 assistance through L4 end-to-end delivery) — **use the wrong metric, and AI stops at "the individual is faster."**

5.7 Two Paths and Three Kinds of Guardrails: Putting Uncertainty Inside the System

There is more than one way to land "AI-native." An academic essay in the *Harvard Data Science Review* relocates the source of efficiency: to unlock the 2–10x productivity potential of agents, enterprises must redesign workflows rather than treat agents as accelerators bolted onto existing processes[8-99]. The Linde case it cites cut audit-report preparation time by 92% — the leverage was not the model but converting a serial process dominated by hand-offs and waiting into one that agents push forward continuously while humans intervene at key checkpoints. Conversely, the reasons pilots stall are highly consistent: an analysis in *Supply Chain Management Review* notes that AI tools are typically "layered" on top of legacy infrastructure and existing processes without redefining the process itself, so demos look good but never reach the P&L[8-100].

In pushing AI from "demo" into "daily routine," the first bottleneck is usually not the model but the toolchain itself. Linear's engineering retrospective is a concrete sample: once agents made writing code faster, CI immediately became the bottleneck — despite the test suite nearly quadrupling since the start of the year, Linear cut pull-request wait time from just over six minutes to just over five, by moving to faster runners, optimizing the jobs that gate other work, and reducing repeated environment setup[8-105]. **When the producing end speeds up, the validating end becomes the new constraint — a narrow gate every "AI efficiency" narrative must pass through.**

Stripe turned that gate into an institution. Its knowledge AI platform, Kai, reached most of the company within two weeks of launch and now has 83% weekly active users (nearly all of GTM). Its design premise is a judgment: coding work could be

handed to agents because compilers, tests, and git supply decades of "fast, verifiable guardrails," while knowledge work has almost no such structure and must build its own[8-101]. Stripe therefore defined explicit invariants — for example, that data from two unrelated customer contexts must never appear in a single analysis — with an isolation boundary framed not as "what can this person access given their authorization" but as "what should this task be allowed to see given its context." Its earlier lesson is equally worth copying: a NoCode agent builder produced more than 4,000 micro-agents of uneven quality that became hard to monitor and maintain, and was eventually consolidated into a platform.

At the infrastructure layer, the answer is standardizing. Tencent Cloud (Chinese: 腾讯云) draws the distinction sharply: microservices are "one service for N users," homogeneous and stateless, while agents are "one agent for one user," heterogeneous, stateful, and autonomous — so elasticity (cold starts, horizontal scaling, cost flexibility), operations (a "pet" model, the opposite of microservices), and governance (unpredictable behavior) all require a purpose-built runtime[8-103]. On the delivery side there is a more mundane lesson: a retrospective drawn from manufacturing and retail clients groups the costs invisible on the quote into three — volatility in model-call fees, context-window inflation, and multi-module orchestration and operations — noting that going from a single-module demo to five to eight production modules makes fault localization complexity grow on the order of N^2[8-104].

Finally, the human side. A closed-door session at the ITValue Digital Value Summit recorded an uncomfortable observation: at Zhishishengong (智识神工), nearly all code is now generated by AI — but when AI coding sharply reduced the team's workload, many members did not shift toward systems analysis, documentation, and knowledge creation as expected. Instead they showed "all-round capability regression"[8-102]. Its founder's judgment is that AI is not a tool but a new labor subject, and that the future organization is a "human-machine union" (CHR) of people plus multi-robot teams — humans managing, deciding, and creating knowledge, robots handling systems analysis, coding, and testing. He also left a line worth pasting on the wall of every transformation project: "The bullet of the revolution hits the revolutionaries first."

When agents actually enter business systems, "turning the GUI into a command line" is far from enough. Alibaba Cloud CIO Jiang Linquan (Chinese: 蒋林泉) breaks the path into two easily underestimated things[8-117]. The first is permission control: a human operating item by item in a GUI is slow, but an agent with excessive permissions can read and rewrite in bulk automatically — "a human can only do

limited damage in the GUI, but an agent's destructive power is ten times greater" — so the principle is that **the data an agent can see, the systems it can call, and the processes it can rewrite must not exceed the user's own permissions**; datasets need fine-grained row- and column-level control, plus auditing so every operation is traceable. The second is "migrating the guiding information": when a human operates a screen, field meanings, selectable ranges, and hover hints implicitly tell them what to do next; once the system is opened to agents, this implicit business semantics must be reorganized into fields, ranges, constraints, and exception handling that AI can understand — Jiang Linquan calls this the **"fence" (围栏)**. The fence also reserves a place for human intervention under uncertainty: "without guidance, AI will pick for you at random, and afterward you won't even know where it went wrong." The interface rework itself is quick (wrapping APIs as MCP took little time); what consumed months was permissions and semantics. **This is 5.1's "redesign first, automate second" projected onto the system layer: before opening the door to an agent, write into the system itself what it may do and how to do it right.**

5.8 Putting Agents Inside the Engineering Loop: Four Companies' Practice

The previous sections described how to shut uncertainty inside a system. This section looks at how four companies actually did it — and what they share is that none of them treated "AI productivity" as a tooling problem rather than a design problem of process and accountability.

Calendly: the loop has durable state, and human checkpoints sit at the right nodes. This scheduling SaaS company wove agents through the whole R&D flow: a Jira ticket or one-page brief defines the problem, constraints and acceptance criteria; an agent reviews it for ambiguity and missed edge cases; a planning agent breaks approved work into PR-sized tasks; implementation agents run in parallel; QA and review agents verify against requirements and the test suite; only then do humans review, approve and merge. Crucially, none of this lives in a disposable chat window — requirements stay in Jira, review history in GitHub, verification results in CI, and behavioral constraints in repository instructions[7-87]. The hardest sample came from the IAM team: roughly 64 PRs in a week and a half (37 merged, 27 in review), covering about 30% of a project to decouple the IAM data model from the monolith, all running under a dedicated Service Identity and still required to pass two human review gates. One signal matters more than the speed: an internal tool let two team

members who had never really shipped code — a designer and a product manager — create and deliver PRs. **Where guardrails and review are reliable enough, the boundary of who can safely participate in software development gets redrawn.** They summarized the shift in one quotable line: the bottleneck moved from writing code to alignment to judgment — "handing a vague ticket to a very fast agent does not get you a correct result faster, only a wrong result faster."

Plaid: turn "things that must not happen" into mechanical blocks, not documentation. All agent configuration is committed to the repository alongside human documentation, so the team shares one environment. Permission and Hooks enforce mechanically — reads allowed by default, `git push` asking every time, `rm -rf` refused outright; formatting and type checks after edits; protected-branch pushes blocked and secrets scanned with secretlint before commit. AGENTS.md loads automatically at session start (detailed material lives in docs, with only an index kept in the file), rules trigger by file path, and Skills and Subagents freeze recurring flows while isolating high-volume intermediate work like review and verification into separate contexts (a db-reader subagent, for instance, is restricted to read-only by hooks). The result: a five-person team moved from roughly 150 pull requests a month to roughly 600[7-91]. Their own summary is worth copying: "the era of reading code is not over, but what you read has changed — you read how intent and constraints were designed, where the judgment boundary sits, and whether the process is reproducible."

AWS's consulting team: split team-wide rollout into five steps, in order. Supporting one development organization's move from individual use to multi-team rollout, they hit four problems with one root cause — output quality depended on personal prompting, agents did not follow established processes, individual know-how was not shared, and review and security verification had never entered the system; all four amounted to "the agent doesn't know how the team works." The buildout ran in five steps: make the rules explicit (fix every repeatedly-explained convention into a file, and always state what "done" means — without a completion criterion an agent reports success as soon as it compiles and skips the tests) → split knowledge and separate roles (keep only prohibitions and musts in always-read files, move detail into on-demand skills; separate implementation and review subagents, with at most two retries before a task goes to a human) → structure the workflow (the main agent only orchestrates and does not implement; inventory assets on a "before/after the task × human/AI" grid, which revealed that the most-missing quadrant was mechanical post-

hoc verification of AI output) → add quality gates (decidable pass/fail, with failure barring entry to the next stage; gates admit only machine-decidable criteria and leave things like UX to humans; run a fixed "eval set" repeatedly rather than relying on a feeling that things got better) → close the learning loop (Hooks record correction instructions at session end as learning candidates, and scaffolding that is no longer needed is periodically removed)[8-123].

Tencent Cloud's delivery retrospective: knowledge cold start eats 40-60% of the time. Drawing on customer cases in automotive manufacturing, hotels, pharmaceutical retail and logistics, Tencent Cloud splits the path from PoC to production into four phases: knowledge cold start (RAG foundations), workflow orchestration (intent and execution), multi-agent collaboration, and governance and operations. The most underestimated number is that **knowledge cold start typically consumes 40-60% of total deployment time**, with highly repetitive failure modes — fragmented formats, mechanical text splitting that loses context, tabular data collapsing into unstructured text, and hard platform ceilings on file size. On the multi-agent side, one hotel group's three specialized agents (internal service, store operations, regional management) cover more than 5,000 hotels and 20 brands, lifting business-scenario coverage from 75% to 100%, cutting FAQ maintenance from over 1,000 entries to just over 100, and reducing new store managers' operational error rate by 60%. On the governance side, one number reminds everyone that cost must be visible: a dairy company's copywriting agent consumes 30 million tokens a day[8-125]. Together the four companies suggest one shared test: **replace the question "can we use AI here?" with "what must a machine verify mechanically, and what must a human sign?"**

One further practice deserves its own paragraph, because it is the precondition that makes the four cases above possible. A roundtable of engineers from Taobao Shangou, NetEase CodeWave and Ping An Technology set out three increasingly clear layers of guardrails: the first turns requirements from prose into structure (SPEC defining goals and constraints, EARS-style sentences turning requirements into verifiable items), the second turns "done" into an executable gate through testing and CI, and the third unifies Skills, Lint, CI and a team constitution into a single "constitution" every agent reads — using tools such as ArchUnit and PMD to turn rules written in Markdown into builds that actually fail[8-129]. Two of their judgments are worth recording alongside: high-complexity, high-precision scenarios are unsuitable for vibe coding; and "the first victims of vibe coding have already appeared — they

need to hire vibe-coding code repair specialists." **Rules only count as followed by agents once they are executable** — the implicit precondition of all four cases in this section.

5.9 Semi-Black-Box Code: Moving Observability from Troubleshooting into Development

This section covers an often-ignored consequence: the speed of producing code has risen, but the speed at which people understand the system has not risen with it.

An engineer who has long worked on monitoring and observability named this state the "semi-black box" — the code is not an unreadable black box, yet implementation details, exception paths, historical compatibility logic and behavior under real traffic can no longer be derived inside an engineer's head[8-127]. Semantic errors are worse: AI readily produces code that is syntactically correct, passes tests, and is not quite right in business terms — and that kind of problem "looks approximately fine," making it the hardest to catch in review. His prescription is to move observability forward, from "look at metrics and logs when production breaks" to part of design, development, review, canary release and release verification:

- every important change ships with its observability: what the critical path is, what metrics a normal case should produce, what logs an exception should emit, whether a trace shows which branch was taken, and whether there is a business-level success rate and latency;
- release is not the end but the start of verification — error rates, latency, resource consumption, downstream dependencies and core business metrics all need to be watched after a change, with anomalies attributable to it quickly;
- engineers must prove themselves with an evidence chain: when the version shipped, whether the error rate changed, whether P95/P99 changed, where the trace stalls, where anomalous log parameters come from, whether configuration changed, whether there are slow queries, whether dependencies are flapping.

This is two faces of the same thing as the guardrails in 5.7: guardrails define what is not allowed, observability defines what entitles you to say it is correct. **Tests prove it can probably run before release; observability proves it is actually running correctly in the real world after release.**

LangChain founder Harrison Chase gives the isomorphic judgment from the agent side: in an agent application, behavior is determined not only by code but also by the model, a black box running outside the code, so the "source of truth" shifts from code to code plus traces — you do not know what is in context at step 14, because the previous 13 steps could have pulled in anything; and precisely for that reason online testing often matters more than offline testing, since behavior only emerges under real inputs[8-128]. He adds one line entirely aligned with this section: when something goes wrong on a team, the first reaction is no longer "show me the code" but "send us that trace."

5.10 Review Becomes the New Bottleneck: More Code, Not More Software

Sections 5.8 and 5.9 describe how to put agents in the right place; this section looks at where the bill lands once they are there.

A study covering more than 700 firms pushes the efficiency account downstream. Harvard researchers Fiona Chen and James Stratton used Jellyfish engineering-productivity data covering more than 700 software firms, over 700,000 employees and roughly 300 million work events (commits, pull requests and the like) from 2021 through March 2026. The finding has two halves. Capacity did rise: after coding agents were introduced, total lines of code rose 30% on average, commits rose 20% and pull requests rose 23%. Output did not follow: the resolution rate of Jira issues and epics showed no statistically significant change, and the size and complexity of those work items did not shift structurally either[1-44].

The increment was absorbed by review. After agents arrived, the average review time from pull request to merge stretched 49%, the share of pull requests requiring changes nearly doubled and comments per pull request rose 35%. At the same time the share of workers performing reviews rose 14% while total active headcount did not change significantly — the organization absorbed "more code coming in" with "more people looking." AI review did not close the gap: by March 2026, 80% of sampled firms used some form of AI code review, yet agents produced only 23.3% of review comments and touched 10.8% of pull requests, leaving the overwhelming majority of judgment to people; 95% of firms had already deployed coding agents.

The capacity ceiling is no longer on the generation side. Calendly's summary in 5.8 — that the bottleneck moved from writing code to alignment and judgment — now has firm-level quantification; the observation in 4.9 that end-to-end demand consumed no fewer people is the same phenomenon at the other end. Three directions follow. Make "what counts as done" a machine-decidable gate so rework happens before submission rather than inside review. Layer the review: formatting, typing, tests and static checks to machines, semantic judgment and accountability to people. And treat reviewers as capacity to be staffed rather than slack to be drawn on. **When the cost of generation approaches zero, the scarcest resource in the organization is the time of people willing to sign their names.**

5.11 The Core Judgment of This Chapter

Workflow redesign is the minimal executable unit of the AI-native organization. Organizational form (Chapter 4) is the skeleton; workflow redesign is the muscle — an organization doesn't need to finish "organizational restructuring" before becoming AI-native; it only needs to start with one workflow: map the real process, delete redundant steps, define decision rights, design for production, measure the whole flow, and iterate in 90-day cycles. **Reduce organizational friction (the denominator) first, then multiply talent and AI leverage (the numerator).** In the next chapter, we take on the hardest variable: people.

Chapter 6 Incentives and Talent: The Hardest Variable to Rebuild

Technical problems all have answers; people problems don't. This chapter examines the hardest variable in an AI-native organization: how to evaluate performance, how to incentivize, and how to develop people.

6.1 Transn's "Energy Gold": Turning Adoption from an Administrative Order into Market Behavior

Transn (Chinese: 传神), a translation company, runs an "Energy Gold" mechanism that is the Chinese benchmark for AI-native incentive design:

> Every time a colleague genuinely uses an AI application and is satisfied with the result, the development team earns Energy Gold — a colleague-validated incentive credit. The more it is used and the higher the satisfaction, the greater the reward. **Judgment rights go to the users; decision rights go to the data.**

The supporting mechanisms are an AI Native decision committee (organized by business line — AI is not the technology department's business, it is each business line's own business) and the DEMO rule (every AI project must have a runnable DEMO and clearly explain which business problem it solves; no DEMO, no meeting — this kills 90% of PPT projects).

The elegance of "Energy Gold" is that it turns adoption from an "administrative order" into "market behavior": colleagues vote with their feet, creating a positive reinforcement loop of "the more it is used, the better it gets; the better it gets, the more it is used."

6.2 Evaluation: From Input to Output

The third of the three lightweight principles for small and mid-sized teams is the most counterintuitive and the most important: **evaluation criteria must change.**

Traditional evaluation looks at hours worked, volume of output, and process KPIs — which is effectively forcing employees to fake using AI. Someone who genuinely knows how to use AI produces more in 3 hours than a non-user does in 10. Evaluation must shift **from input to output, from process to results**.

> If you don't touch evaluation, AI adoption is empty talk — you are touching the root of the entire management system.

International samples are changing evaluation too: Shopify includes AI usage in performance reviews, and its CEO memo requires employees to "first prove AI can't do this job" before applying for additional headcount[7-19]; Duolingo's AI-first memo likewise included using AI to evaluate employee performance[7-52] (though it later sparked controversy).

6.3 Tencent Research Institute: Reviews Give Way to Calibration and Four Dimensions of Incentives

The Tencent Research Institute report takes a more radical position: **"reviews" largely retire inside Super-Teams; management action shrinks from "control" to "calibration."**

> When information is transparent enough and individuals are strong enough, management action contracts from control to calibration — the rest is left to people and agents to run on their own.

Super-Individuals do not lack capability; what is scarce is "why invest time here." The four incentive dimensions (all indispensable — an imbalance in any one leads to attrition or downgrade):

Dimension	Mechanism	Case
Autonomy (most cited)	You decide what to do and how	Block's DRI system — for 90 days you are the CEO of this problem. "Power incentives first, money incentives second"
Growth environment	High-density peers + sense of mission	Kimi: all 300 people see themselves as AGI builders; no OKRs, no KPIs, no clocking in

Dimension	Mechanism	Case
Economic return	How output is fairly priced (the hardest)	Three explorations: Anker Innovations, Tenex, Pure Global
Freedom to exit	Retain people by being worth staying for, not by lock-in	Netflix: options vest immediately with no lock-up period

Economic return is the dimension the report admits it cannot solve: "How can a 10–100x efficiency gap be reflected in a compensation system? No company has yet given a replicable answer." Traditional pay is tied to rank and role, but once AI flattens execution capability, the value of judgment and creativity rises sharply. "10x output rewarded with only 1.2x pay" → either leave and start a company, or reduce your effort — either way, the organization loses.

One reverse warning (ColaOS): **"organizations that make efficiency gains their core metric end up laying people off; organizations that make revenue growth their core metric end up expanding"** — the best incentive for a Super-Individual is "your high-output work opened up new business space, and you get to share in that growth."

6.4 Super-Individuals and the Competitiveness Formula

The Tencent Research Institute gives four structural characteristics of Super-Individuals (see Chapter 3): an AI-first work pattern, order-of-magnitude jumps in capability boundaries, strong proactivity, and influence spillover — **an efficient individual only makes themselves faster; a Super-Individual makes the team faster.**

The competitiveness formula: **organizational competitiveness = talent density × AI leverage ÷ organizational friction.**

The corollary for talent strategy: shrink the denominator (organizational friction) first, then multiply the numerator (talent density × AI leverage); halving the denominator is equivalent to doubling the numerator. Hiring structure follows the HBS evidence: a higher share of engineers, fewer entry-level roles, half the management layers — **invest the budget in senior all-rounders.**

The reshuffling of capability rankings: AI amplifies underlying capabilities (logic, rapid learning, problem decomposition, systems thinking) — only people who were already excellent become more excellent, and the gap widens. What is actually being repriced is the layer beneath skills: **judgment, learning speed, problem decomposition, taste** — while the existing talent system measures almost entirely the layer that is depreciating.

The World Economic Forum's *Organizational Transformation in the Age of AI* white paper (based on a survey of more than 450 executives) offers a scalable playbook on the talent side[1-38]: Yum China uses an AI recruiting platform to match millions of applicants, covering about 89% of restaurant hiring needs across 16,000 stores, with an average time-to-hire of just 1–2 weeks and restaurant-manager turnover falling from 9.7% to 7.8%; Unilever uses an AI internal talent marketplace to match employees to short-term projects, achieving 70% cross-functional task allocation, releasing roughly 500,000 hours of capacity, and lifting productivity by 41%; Johnson & Johnson uses AI to infer employee proficiency across 41 future skills, combining learning activity and internal experience data into a "skills heat map" that raised usage of the learning ecosystem by 20%; and Repsol's human–AI collaboration model runs 22 AI agents across 38 use cases handling discrete tasks, gathering input, and checking compliance, while humans retain review and approval[1-38]. **What these practices share is replacing jobs with capabilities and treating change as a permanent capability rather than a one-off project.**

6.5 The Skills Gap: The More AI Is Used, the More "Hollowed-Out" Organizational Capability May Become

This is the most hidden long-term risk of the AI-native organization.

Anthropic's internal research (December 2025) offers two-sided evidence[8-40]: engineers become "full-stack" and learn and iterate faster because of AI, **but at the same time worry about deep skills atrophy** — "when output is so easy and fast, actually taking the time to learn something becomes harder and harder"; 27% of AI-assisted work is exploratory work they would not otherwise have done (the good news), yet employees also worry that "one day AI will automate me out of a job."

WEF 2026: up to 75% of entry-level jobs in East Asia are disrupted by AI; up to 60% of entry-level tasks can already be taken over by AI[8-38], and newcomers to the workforce lose their "practice ground" — cutting only entry-level roles severs the pipeline for talent development and innovation.

The essence of the skills gap is a choice between "treating AI as a crutch or as a trainer":

- Let AI fully take over (employees lose practice opportunities) → skills gap;
- Use AI to accelerate learning (AI as sparring partner, explainer, boundary-expander) → organizational capability compounds.

Anthropic has already made "how to prevent skill atrophy" a formal research topic. **The psychological cost of AI-native work is real** — internal employee communications mention "about 5 months without hand-writing code" and "feeling meaningless when everything is automated." Organizations need institutionalized "learning preservation" design.

Overseas research has now quantified the "crutch or trainer" question. The *Widening Gap* study cited by JetBrains frame-by-frame analyzed novice programming behavior: novices who leaned heavily on AI assistance "skipped crucial planning stages" and finished with an "illusion of competence" rather than true understanding; the best-performing novices were those who heavily limited or outright ignored AI assistance — they developed "negative expertise": the ability to identify and ignore incorrect or unhelpful AI suggestions. A University of Pennsylvania 2025 study of 1,000 students found that students learning math with an LLM performed 17% worse than students with only a textbook — while believing they were excelling; in the same study, a "GPT Tutor" group that used the model as a Socratic sparring partner (attempting problems first, asking for help when stuck) performed 127% better[8-79] in practice sessions — **friction itself is a necessary condition for forming expertise**. Anthropic's 2026 study on how AI assistance affects coding skill formation reaches the same conclusion: "Cognitive effort — and even getting painfully stuck — is likely important for fostering mastery."

The other face of the skills gap is the **right to refuse**. An employee at an Australian sports organization resigned[8-78] after her request to opt out of Copilot was denied in writing ("you are not entitled to ask that your work not be accessed by our AI systems"); surveys show roughly 35% of employees are uncomfortable with AI adoption, and an individual's exit neither stops the AI nor stops "employees training

the AI that replaces them." An organization that designs only "how everyone uses AI" but not "who has the right to refuse, and what refusal costs" will see hollowing-out take another form: talent voting with their feet.

NBER's working paper supplies the other half of the skills gap — **the loss of meaning** (see Chapter 3)[1-37]: automation can reduce the value of work before it eliminates the job, and the meaning that comes from the outcome depending on my contribution is eroded by a credible machine substitute. This explains why "people are still here, the work is still here, but people have started to feel superfluous" is an earlier signal than layoffs. ByteByteGo names its organizational consequence the **junior pipeline hollowing**: when human verification is outsourced to agents, the development experience of early-career developers degrades first, and the missing rung becomes a long-term sustainability risk[7-75]. That points to a concrete institutional design: **if AI takes over the practice field, the organization must build another one** — treating working with AI as an explicit, teachable, assessable, and promotable capability rather than assuming employees will pick it up.

The data on the talent pipeline became clear in 2026. PwC's *2026 Global AI Jobs Barometer* for mainland China, based on more than one billion job postings across 27 countries and regions, introduced an "AI Occupational Exposure" (AIOE) index to measure how much of a given occupation's tasks AI can currently perform. Its conclusion: occupations with high AI exposure remain the main source of job supply, but **skills are being transformed faster than jobs are being replaced**, and companies' focus is shifting from "hiring AI talent" to "raising AI capability across the workforce"[8-107]. That finding runs directly against treating headcount as the only variable.

The real risk is not the total but the entry point. Korn Ferry's *2026 Talent Acquisition Trends* report lists "cutting entry-level roles equals dismantling the talent pipeline" as a standalone trend: the junior and operational roles being eliminated are the cradle of future managers — a junior analyst who spends two years learning the whole business grows into a junior manager, and a coordinator who knows every process may become a team lead. The report also notes that younger junior employees are precisely the fastest adopters of new technology, so a short-term cost reduction buys a succession crisis[8-106]. KPMG's survey of Hong Kong organizations shows the other face of the same divergence: the share of organizations with widespread AI adoption rose from 8% in 2025 to 24% in 2026 — roughly tripling in a year — while recruitment pivoted toward revenue-generating roles[8-108]. **The depth of**

AI use is stratifying: most organizations remain at individual use, while a minority have embedded AI in core processes and are re-sorting their hiring structure accordingly.

On the engineering side the pipeline crisis is quantified most bluntly. At Cloud Next 2026, Google disclosed that nearly 75% of its newly written code is AI-generated and reviewed by human engineers (15% two years earlier, 25% a year ago, 50% in autumn 2025), and that one complex code-migration task completed jointly by agents and engineers ran six times faster than pure manual work a year earlier. In the same period, a Sonar survey found 72% of developers using AI programming tools daily, with AI-generated or AI-assisted code at 42% (6% in 2023)[8-110]. But the counter-evidence in the same materials is just as hard. Faros AI's telemetry across more than 4,000 teams and 22,000 developers found that once a team crosses the threshold of 50% weekly active AI users, tasks completed per developer rise 34% and epics completed rise 66% — while coding-related tasks surge 210%, bugs per developer rise 54%, the incident-to-pull-request ratio more than triples, median code review time increases fivefold, and 31.3% of pull requests are merged without any review. The researchers call it an "acceleration shockwave." Thresholds on the talent side moved too: demand for junior developer roles is down 67% since 2022, and Harvard research found employment among 22–25 year-olds in AI-exposed occupations fell about 13% after GPT-4 arrived, while senior roles kept growing. **Between accelerating output and the organization's capacity to absorb it, a narrowing entry point is turning into a structural gap.**

6.6 Innovation Density: The Organization Wins

DeepSeek: 160 people vs OpenAI: 3,500 / Anthropic: 3,000 / DeepMind: 8,100; Moonshot delivered a trillion-parameter model with 300 people and 1% of the industry's compute.

> **In the AI era, more people does not mean stronger — innovation density is the ultimate competitiveness, and innovation density is not built by stacking people; it is engineered through organization.**

This fully corroborates the Tencent formula: high talent density × high AI leverage ÷ low organizational friction = 160 people beating 3,500.

6.7 Enable vs Replace: A Debate Already Settled by the Data

On the relationship between AI and people, there are two strategies:

- **Replacement automation**: positioning AI as a tool to "cut headcount, cut costs, boost efficiency" — breeds employee resistance, collapsing trust, tacit knowledge loss, and stalled innovation; it looks like saving money in the short term but destroys core organizational capability in the long term;
- **Augmentative collaboration**: AI handles the transactional layer while humans focus on judgment, creation, and relationships.

The data has already settled the debate:

- 2026 Gallup and PwC research: an **"enable employees" strategy can raise retention by about 32%**, with innovation capability and performance significantly ahead;
- Asana (2025): 64% of employees consider AI agents unreliable[8-34] and call for more training, clarity, and guardrails — nearly half of employees are anxious about job loss (Accenture);
- Microsoft WTI 2026: **organizational factors (culture, manager support, talent practices) contribute 2x as much to AI impact as individual effort**[7-71] — employees are not the bottleneck; the organization is;
- Business Week (2026): 55% of companies that laid people off because of AI regret it (Orgvue survey).

6.8 Role Fusion: Those Who Own Results Should Not Be Boxed in by Job Titles

The biggest obstacle to enterprise AI adoption is not technology but organizational inertia[8-73]. Traditional organizations function on two premises: work can be fully divided into standardized nodes, and employees only need to be responsible for their process node while the organization backs the final result. AI changes exactly these premises — when document work, design, and parts of coding can be done by AI at lower cost and higher stability, the value of many roles is revalued and role boundaries blur: a product manager builds a demo with AI, a designer generates front-end pages directly, a developer joins product judgment with AI's help.

This is not one role replacing another — it is **Role Fusion**: the people who will be more valuable are no longer responsible for a single process node but can go from a user problem to full implementation and own the final result. The disruption follows: one person can span steps that previously required handoffs and produce something much closer to the outcome, yet the organization still manages people by job title, breaks tasks down by process, and accepts deliverables by node — "the people who actually get things done take on more responsibility but are still evaluated inside their old job boxes."

Role Fusion must be paired with results-oriented incentives, changing three dimensions at once: **authority** — give fused roles decision rights that span steps; **reward** — allocate by final results and user value rather than job level; **growth** — provide career paths that cross traditional functional boundaries. Otherwise the people who truly achieve Role Fusion will quickly feel the unfairness, and most will leave for teams that can recognize this kind of capability.

The hiring market already shows the corresponding gap: enterprises do not want people who can call APIs and write agent loops; they want people who can turn model capability into **stable services** — monitoring, evaluation, iteration, cost, latency, stability, and human review after launch each require engineering discipline; the real bar is turning a demo into a low-latency, observable, maintainable service that can enter enterprise processes. That is why the hybrid roles in demand are the **product engineer and the business-minded technical consultant** — they may not only know models, but they know how to turn a vague requirement into model inputs and outputs, translating back and forth between business and engineering.

Role fusion also needs an organizational handle. The **Agent Champion** model is worth copying directly: each pillar names one or two full-time Agent Champions who spend 50–100% of their time reshaping workflows, preparing codebases, and restructuring operating models — not a side-of-desk assignment but a dedicated role for high-agency technical leaders, with champions for product, design, and analytics (a product champion redesigns reviews and experiment flows, a design champion builds agent-first prototyping frameworks, an analytics champion lets agents run analyses on an AI-native data foundation)[7-75]. The companion mechanism is the **Single Task Owner (STO)**: every initiative has one owner with clear priority, authority, and decision rights — "most dysfunction in AI-native organizations comes from unclear ownership, not bad process." Leadership capability moves up

accordingly: from delegation to orchestration, with technical depth non-negotiable and context engineering becoming a core leadership skill — **the precision of the guidance you give AI is the precision your teams inherit**[7-75].

The most copyable practice on the talent side is an experiment with a control group. At HR World Summit 2026, 94% of CEOs said they would maintain or increase AI investment, while the conference's judgment was that roughly 60% of core business processes could be automated by autonomous agents — which means the subject of discussion has shifted from "AI replaces some work" to "how the work people do is itself changing"[8-109]. The Spanish energy company Naturgy turned that into verifiable engineering: it made AI a top management theme, set up a competence center jointly staffed by HR and IT/digital, and pushed along three layers — small efficiency improvements, organizational structure and hierarchy, and the division of labor between people and machines. More importantly, **it ran 300 AI Copilot users against 300 non-users and evaluated them on 25 KPIs including creativity and responsiveness, rather than asking whether it "felt useful."** The result: per-capita time created rose from 121 to 183 minutes per week, and output quality improved 16%. **When an organization's AI return can be written as "minutes per week and percentage points of quality," it earns both the legitimacy to keep investing and the conditions for replication — and that is precisely the step most companies skip.**

6.9 The Fear of Being "Forever Junior": Four Skills You Can Practise Yourself

The skills gap has a subtler face: it is not that veterans get replaced, but that newcomers never get the chance to become veterans.

A junior engineer wrote that fear down plainly — what should actually scare us is not software engineering disappearing, but senior engineers disappearing, leaving everyone "forever junior": one agent reviewing another agent's output, with nobody left who can say from experience, "this part is wrong"[8-131]. Her response was to decompose "senior" into practisable behaviors and name four capabilities that depend on no tool permission at all:

- **Curiosity**: let the agent quiz you back with Socratic questions — it costs more tokens and buys "I actually understood this before it shipped" instead of "it seemed to run";

- **Emulation**: treat the accumulated review comments of senior engineers as a training set, abstract the patterns specific to the team and the field, review the agent's first draft against those patterns yourself, and only then hand it up;
- **Autonomy**: deliberately and occasionally make one small change by hand without an agent, to keep architectural sense, a feel for algorithmic complexity, and intuition for token efficiency alive;
- **Collaboration**: write the problem out clearly yourself before going to a senior rather than forwarding an agent-drafted message and answer — because articulating the problem *is* the junior engineer's main growth motion.

Her conclusion is more useful to organizations than to individuals: curiosity, emulation, autonomy and collaboration are not things an agent can give you; they come from what you choose to do while the agent is running. **If AI occupies the practice ground, the organization has to build another one** — while handing repetitive work to AI, it must re-lay-out how beginners acquire judgment. That is the missing half of the answer to the gap described in 6.5: the gap is not closed by using AI less, but by re-allocating which work must stay with a human beginner.

6.10 Rewriting Roles: the Squeezed Middle of Professional Services and Banking's New Job Families

Chapter 4 discussed "job consolidation"; this section looks at three places where roles are being rewritten.

The middle of the professional-services pyramid is being compressed. A discussion among legal-industry leaders put it plainly: technology is compressing the middle of the pyramid, with AI, talent and pricing acting at once, stripping the traditional structure — where a large cohort of mid-level lawyers carried work upward and knowledge downward — of its economic basis; years of investment in mentorship programs are, on the data, not enough, and what must be redesigned is the development path itself[10-283]. Consulting says the same thing differently: the hourly-billing model is degrading and the traditional pyramid is being upended, because consulting's core value proposition rested on trained people being scarce — and when knowledge and analysis become abundant, scarcity is no longer where it was[10-284]. Together they show that **once the economics of the middle layer are pulled out, "bringing people along" can no longer be left to naturally occurring apprenticeship; it has to become a system with roles, metrics and budget.**

Banking's new job families are not "more senior versions of old jobs." A banking digitalization research outfit argues most banks get reskilling wrong: the gap is not "training existing staff to do the same work" but "redesigning what people should do and which work does not yet exist"[10-289]. Banks' traditional role architecture was built around tasks (analyst-manager-director); AI commoditizes tasks, leaving work that orchestrates multiple agents, multiple data sources and multiple stakeholders into one coherent output. The roles that follow — agent operations lead, model governance officer, AI risk underwriter, decisioning systems architect — do not map onto existing job families at all: the shape of the work is different, neither more senior nor more technical. The UK Financial Services Skills Commission supplies the other half of the picture: some roles shrink, and **the foundation of entry-level roles is damaged by AI, which may weaken the talent pipeline**, so beyond reskilling what is needed is redesigning roles and progression paths[10-288].

Both threads point to one conclusion: **in industries that grow people through a middle layer, job families and development paths must be rewritten together** — rewrite only one and the ladder snaps in the middle. This is the same mechanism seen in different industries as the hollowing of junior talent pipelines in 9.4 and the transformation of professional-services firms in 10.1.

One more emerging role belongs here. Return to the definition of software engineering — using software to solve problems rather than writing code — and an old job returns under a new name. A "product engineer" translates business needs into software requirements without personally writing the software; one dataset counts more than 1,300 open FDE-style roles across 565 companies at roughly $240,000 average total compensation, and the author expects this role to become mainstream software engineering within two to five years[8-132]. The implication for this book has two layers: the ability to define the problem is being priced separately for the first time; and the hazard the author flags — when everyone is asked for "high agency," the ladder by which junior people acquire agency is the first thing to snap (the same root as the junior-pipeline problems in 6.9 and 9.4).

6.11 Quality Ownership and Hiring Bars: the Responsible Party Is Changing

Section 6.10 described roles being rewritten; this section looks at the same shift at two entry points — quality and hiring.

Quality assurance did not disappear; the party doing it changed. In the second half of 2026, parts of ByteDance began moving QA staff onto the R&D job family, with some teams merging the QA and RD tracks outright. The change is being rolled out in waves — some teams this year, others next — and the RD track carries higher requirements: some people have to pass a new interview, and those who cannot may leave. Similar adjustments have appeared at Ant Group, Alibaba and Meituan over the past two years, all in the same direction: test organizations shrink, job families merge, quality responsibility moves to R&D. The cause is not complicated: AI coding lowered the bar for writing unit tests and automation scripts to something a developer can do in passing, while cost pressure forces organizations to redraw job boundaries. The substance of the merge is a higher entry bar — from "can execute test cases" to "can write code, understands systems, and can use AI to do the work faster"[7-96]. **The adjustment is so far limited to parts of a few large firms, but it yields a generalizable judgment: when tools take over execution-layer skills, organizations do not keep the old role and retrain it — they hand responsibility to whoever sits closest to the output.**

The hiring standard is moving at the same time. HackerRank's CEO publicly acknowledged that the company helped standardize technical hiring into a form of "grinding problems for months," a format that measures how well a candidate prepared for interviews rather than whether they can build software. Its 2026 changes relocate the standard on three axes: tasks move from algorithmic questions to real work in code repositories, evaluation moves from code correctness to AI fluency and judgment, and the candidate environment moves from an IDE to an agentic development environment. The interview questions follow — why this approach, what would you change, how did you validate the AI-generated code[8-133]. Algorithmic questions still have value; what changed is their weight in the total. This is the same direction as the four self-practisable capabilities in 6.9: retrievable knowledge no longer acts as a filter, while "can tell whether the AI output is right" does.

The cost lands at the entry point. An analysis carried on the World Economic Forum's Chinese site cites Harvard research: at firms that adopted generative AI, junior employment fell 9%, and entry-level hiring per quarter has dropped 80% since 2023; ZipRecruiter data show the entry-level share of postings falling from over 44% three years ago to 38.6% in early 2026. In the same survey, Gen Z respondents report the highest rate of AI-driven role transformation (38% say AI has fundamentally changed the capabilities their jobs require) and yet are the least likely to receive

formal training — 59% of Gen Z employees who use AI at work say their organization never provided any[1-43]. Entry-level jobs are, in essence, structured learning environments; once the tasks are automated, the organization sees efficiency and loses the path that produced its managers. The prescription is worth copying into workforce planning: turn the tasks AI takes over into "judgment loops" — inspect the output, test the assumptions, stress-test the result, escalate the edge cases — and rebuild the apprenticeship with structured responsibility channels and rotation programs.

6.12 The Core Judgment of This Chapter

The direction for restructuring incentives and talent is clear: **evaluation from input to output, incentives from position to results, management from control to calibration, talent from quantity to density, AI from replacement to enablement.** No single dimension can be solved by "just paying more" — but for every dimension, a set of organizations has provided reference answers. In Chapter 9 we will see: organizations that do not address the people problem are doomed to fail their transformation.

Chapter 7: Case Studies — AI-Native Organizations in China and Around the World

This chapter is the factual foundation of the book. Every case covers organizational form, on-the-ground practices, quantified results, and controversies and dissenting voices. **Official claims and third-party verified reporting are labeled separately** — because in the AI-native narrative, the tension between the promotional surface and the factual surface is itself the most important research material.

7.1 Chinese Cases

Transn (Chinese: 传神) — "Rather Than Wait for Employees to Become AI Experts, Grow AI Capability into the Organization"

Translation company Transn's AI-native practice is the most complete Chinese model available today. It runs on several key mechanisms:

- An AI Native decision committee organized by business line (Language Intelligence Group / Industry Intelligence Group / Brand & Sales Group), each with a clear lead and clear progress goals — AI is not the technology department's business; it is each business line's own business;
- A "DEMO rule": every AI project must have a runnable DEMO and clearly state which business problem it solves — this one rule killed 90% of PPT projects;
- An "AI joint fleet": 20+ cross-departmental business teams build their own AI applications, so that AI applications grow inside business scenarios from day one;
- Backed by the "Energy Gold" incentive mechanism — a colleague-validated incentive credit (detailed in Chapter 6).

Founder He Enpei's judgment: **"Rather than wait for employees to become AI experts, it is better to grow AI capability into the organization."** Individuals come and go; organizational capability stays.

Huawei / Alibaba / Feishu — Three Common Traits of Organizational AI-ification

- **Huawei**: AI embedded across the entire data lifecycle, with intelligent analysis becoming the default capability of the data platform ("You don't go looking for it; the system delivers it to you");
- **Feishu (Lark internationally)**: a collaboration suite connecting IM, documents, and business flow, with AI intervening in project milestones in real time rather than summarizing afterward;
- **Alibaba**: AI-informed decisions replacing experience-based decisions — as data flows through, AI automatically analyzes, warns, and pushes decision recommendations.

DeepSeek — The Ultimate Example of Innovation Density

160 people built a trillion-parameter model. Compare with the scale of peers: OpenAI 3,500 people, Anthropic 3,000, DeepMind 8,100. Organizational design (rather than stacking headcount) determines innovation density — this is the strongest case for the "innovation density" thesis of Chapter 6.

Jingzhunxue (Chinese: 精准学) (Yang Renbin) — The Organizational Brain

Injecting the highest cognition into the front line: AI Chief of Staff + decision model index + context engineering. AI coding is only 0% or 100% (engineers are not allowed to modify code themselves; humans only provide feedback); anti-documentation, anti-group-chat; Context is Everything. (See Chapter 4 for details.)

MarsWave (Chinese: 火星电波) — Completing an AI-Native Transformation in 5 Weeks

The OPC model (human judgment / AI code / manager macro-decisions) + Soul Team (personality and emotional output) + a unified repository as the AI's context + a rhythm of front-load thinking and back-load review. (See Chapter 4 for details.)

Mininglamp Technology (Chinese: 明略科技) — Six Patterns of Enterprise Multi-Agent Collaboration

Mininglamp was one of the first Chinese vendors to productize "multi-agent collaboration," and its architecture guide published in 2026 offers the most complete enterprise-level multi-agent collaboration design framework to date, mutually corroborating Anthropic's multi-agent research in Chinese and English.

Three-layer infrastructure: a unified identity registry (every agent has a unique identity and permissions), a shared context mechanism (converging unstructured discussions in IM into structured knowledge: brief / timeline / deliverables / rejection records / acceptance status), and a task orchestration engine (split / serialize / parallel / compete).

Information topology controls visibility — "see each other when they should, stay blind when they should": a payroll agent should not broadcast its intermediate results to a weekly report agent. Group-chat-style information architectures can only achieve "everyone sees everything"; they cannot deliver programmable visibility boundaries.

Six collaboration patterns (nestable and combinable): Solo (working alone); Roundtable (mutual visibility — all agents share context); Critic (generate-review, with the reviewer holding veto power); Pipeline (strict serial — upstream output is downstream input); Split (divide-and-conquer in parallel — subtasks stay blind to each other and merge after each delivers); Swarm (competition selects the best — multiple candidates produce in parallel, redundancy traded for quality).

Implication for organizations: multi-agent is not "opening a few more windows" — you first decide the information topology and collaboration patterns, and only then talk about model capability. This aligns with the conclusion of the Anthropic multi-agent experiments in Chapter 9: **coordination does not naturally emerge from stronger intelligence.**

New data from mid-2026 continues to confirm this direction: IDC reports that 68% of leading enterprises put autonomous agents on their IT procurement priority list, yet more than 60% of pilots remain stuck at the production stage; a CAICT (信通院) survey of 358 enterprises found 67% reporting "coordination costs higher than expected." In July 2026, Beijing issued the first provincial-level agent policy, setting three bottom

lines — "traceable, auditable, controllable" — with up to CNY 100 million in industry support[8-81]. Organization-level multi-agent collaboration is moving from vendor practice to a regulatory topic.

Lenovo (Chinese: 联想) — "Silicon–Carbon Symbiosis": the Super-Individual Is the Starting Point, the AI-Native Organization Is the Destination [official claims + third-party verified]

In June 2026 Lenovo upgraded its enterprise agent platform Lexiang (Chinese: 乐享) to version 4.0: more than 7 million monthly active users, over 1 million daily interaction requests, and cumulative sales pulled in excess of 5 billion yuan; the "agent corps" helped Lenovo China's direct-to-customer business grow 33% year over year[7-73] [third-party verified]. On the organizational logic, Lenovo's HR leader proposed "silicon–carbon symbiosis" — silicon-based employees handle high-volume, standardized, repetitive tasks, while carbon-based employees focus on complex decisions, strategic design, and human care; the more widely quoted formulation comes from Zhu Li of Peking University's National School of Development: "the Super-Individual is the starting point; the AI-native organization is the destination." Lenovo is also systematically absorbing "AI natives" and spreading an AI mindset across all staff, pushing human–machine relations from "assistance" toward "co-creation." This path represents a typical choice for large manufacturing-plus-channel enterprises: rather than pursuing one-step organizational restructuring, first let super-individuals and the agent corps produce measurable results, then let those results drive the reorganization of division of labor and incentives.

WeBank (Chinese: 微众银行) — Treating Digital Employees as Posts Rather Than Tools

This internet bank has onboarded more than 80 digital employees, online 24/7, and they are not chatbots but "digital colleagues" that complete concrete work across many roles bank-wide. A research-and-development digital employee, for instance, covers the full pipeline from receiving requirements and decomposing tasks to generating code and testing and releasing it, cutting the launch time for a security work order from roughly two weeks to 30 minutes — more than a tenfold improvement[7-82]. Behind it sits an AI engineering platform (computing power that can be reallocated, models that can be swapped, outcomes that can be measured) and the systematic buildout from infrastructure to toolchain under its "AI-native bank"

strategy[7-82]. The organizational meaning of the case is "post-level takeover": digital employees are written into the organization as posts rather than tools, so their responsibility boundaries, workload accounting, and collaboration interfaces have to be defined. It also suggests a sequence — agents run most easily where the work is procedural, verifiable, and has a clear deliverable (R&D work orders, operational review), not where it requires multi-party judgment and negotiation.

China Life (Chinese: 中国人寿) — More Than 500 Agents Across Five Domains

More than 500 agents span five domains — underwriting, claims, risk control, marketing, and agent-force management. On the claims side, large models handle receipt recognition, liability determination, and anti-fraud automation; on the force side, "AI private tutors for agents" and sales-support agents generate training material and customer-management advice, directly changing how a million-strong agent force works[7-83]. Insurance is a data-intensive, process-heavy industry, so the number of agents has become a new indicator of how AI-native a firm is. What matters more is how it treated people — not replacing agents, but arming each agent with AI, converting a "sea of people" into human-machine collaboration.

Alibaba Cloud (Yunqi Conference) — "A Collection of Super-Individuals Does Not Necessarily Become a Super-Organization" [third-party verified]

The AI-Native Organization forum at the September 2026 Yunqi Conference put the CPO line and the CIO line on the same stage for the first time — in the words of Alibaba Chief People Officer Jiang Fang (Chinese: 蒋芳), "business systems are being rewritten by AI, and so the organization will inevitably be rewritten; the people who run business systems and the people who run the organization sat together for the first time." She offered a judgment that has since been widely quoted: "Today an engineer's coding efficiency can rise tenfold, yet the end-to-end development cycle has not shortened noticeably. **A collection of super-individuals does not necessarily become a super-organization.**" That line hits exactly the crack Chapter 5 keeps emphasizing: individual efficiency gains do not automatically translate into organizational effectiveness — between them sit process, collaboration, and decision mechanisms. From this she drew three starting principles — leaders must get in the water first, not stand on the bank; pilot in a special zone rather than

expecting everyone to march in step; redesign the workflow rather than grafting on tools — and cited the QoderWork team in Hangzhou: five people, seven days, with the design discussed, decided, and revised on the same day[7-84].

Alibaba Cloud CIO Jiang Linquan put numbers on that crack: a year and a half earlier his team's AI code-generation rate had already exceeded 40%, yet the people consumed by end-to-end requirements did not fall accordingly — a mass of code that had not been tested, senior-reviewed, and validated in production instead became technical debt, making key people the new bottleneck. His fix was to collapse jobs (see 4.9) and open the systems to agents: first govern business concepts, data dictionaries, APIs, permissions, and identity, then expose the capabilities covering most of the call volume; four months after opening up, general-agent call volume grew roughly 1,000x. The team deployed 28 categories of digital employees over three years, "equivalent to extending the business teams 2,000 headcount," for an investment "far less than the annual salaries of those 2,000-plus headcount" — the website AI assistant turned inquiries that took five hours to close into 10-second responses, and phone QA went from 2% random sampling to full-volume inspection[7-86]. The HR lead on the same stage split the AI-native organization into three stages (personal assistant → digital employees joining the collaboration network → settling into a continuously learning "organizational brain"), disclosed that Alibaba Cloud is in the second stage with more than 600 internal digital employees, and described a roughly 2,500-person team that moved from a traditional functional structure to three tiers of business units over three years, with people handling judgment and value choices and AI handling reasoning and execution in a "dual-core," plus an executive digital twin, "Patrick," that hundreds of employees consult daily. The cross-industry commonalities the roundtable surfaced were summed up by the moderator in six words — **emerge, select, replicate**: there is no single template, but they all move from individual tools to organizational systems, from local efficiency to end-to-end results, and from fixed jobs to "new work units made up of people and digital employees."

NetEase (NetEase Zhigi) — Nearly 100% of Employees Use an AI Agent: "Installation Rate Looks Great, Usage Rate Looks Thin" [third-party verified]

If Alibaba Cloud's sample shows that "super-individuals do not equal a super-organization," NetEase Zhigi's retrospective drops that line into the concrete pitfalls of execution. The company has an AI agent for every employee from R&D to customer service, from operations to management, making it a rare firm where nearly 100% of staff use agents; yet its deputy general manager admitted that the early push fell into an awkward spot — "the installation rate looks great, the usage rate looks thin": 30–40% of skills were being reinvented across teams, tools were scattered across platforms and could not be reused, and many skills lacked a unified data interface[7-85]. The fix was not to keep pressing the business to "hurry up and use it" but to build the road first: a data-access layer that unified the APIs of core systems such as CRM and BI, then a middle platform that sedimented common capabilities like document processing and information aggregation into atomic skills. Only after the infrastructure was in place did they tackle "people," forming a three-level evolution — company-wide literacy to build AI habits (LV1 individual efficiency) → super-individuals independently building business agents (LV2 business efficiency) → cross-functional flexible squads moving from "usable by an individual" to "usable by the organization" (LV3 organizational reshaping, with a "one supervising agent + N functional agents" multi-agent collaboration system). They distilled the governance lesson into one sentence: **"Don't treat the agent as a tool; manage it as an employee"** — the Gateway is the receptionist, the Main Session the supervisor, Sub Agents the execution team, Skills the skill certificates, Memory the work log. This case fills in a lesson the book keeps stressing: the barrier to company-wide AI is not "install it" but "the road" (data and interfaces) and "raising it" (governance and reuse) — the former is engineering, the latter is organization.

More Chinese Practice

Jimo (Chinese: 极摩) (AI-native organizational architecture), Moka (AI-native HR: 3 AI colleagues), Atlassian's China practice (AI-native PM) — case details in Chapter 4 and the appendices. **ICBC Wealth Management and insurance asset managers: treating "one unified entry point plus an agent matrix" as organizational engineering [third-party verified]**

At the 2026 China Banking, Insurance and Asset Management Forum, ICBC Wealth Management (Chinese: 工银理财) framed its AI transformation as three things: build one unified AI entry point; build a "super-agent plus specialized agents" matrix; and make legacy business systems AI-native — with an explicit human-machine boundary: "AI assists analysis, seeing fast and calculating clearly; humans decide, thinking deeply and deciding accurately; systems execute, executing steadily and controllably." The efficiency contrast is concrete: an industry weekly report that used to take a researcher three to four hours now comes out in minutes, with multi-dimensional data, charts and analytical judgment. New China Asset Management's three-layer architecture is another drawing of the same idea: a digital foundation (breaking internal silos, aggregating research reports, filings and ledgers) → an agent system (using big data, large models, chain-of-thought and the MCP protocol to build a "digital investment research and risk-control team on call") → full-scenario applications (research reading, earnings commentary, Q&A and voice analysis; risk-side sentiment, early warning, look-through, grading and verification). In the same discussion, institutions listed AI itself as a new source of risk — model hallucination and open-source model supply-chain security — and made "bringing AI into the enterprise-wide risk management framework, balancing enablement and risk" a precondition[10-176]. **Large financial institutions are converging on the same organizational choice: skip point tools, build the unified entry point and agent matrix first, then redesign processes and boundaries — which is precisely the line between "AI-native" and "an AI project."**

SANY Heavy Industry (Chinese: 三一重工) — A GPO Architecture: Let Business Owners Run AI [third-party verified]

The cases above describe how AI capability grows into an organization; SANY Heavy Industry supplies the other half: **who owns the success or failure of AI.** It made AI transformation a group-level top strategy rather than an IT side project, and the accompanying design is rare — a GPO (general business owner) mechanism: each of the four core domains (R&D, supply chain, manufacturing, sales & service) has a senior business leader as its GPO, IT cannot parachute in to take over, and the business decides how AI is used while owning the outcome[7-93]. The rollout order is equally counterintuitive: start with must-have applications such as operating dashboards and an after-sales assistant, then let real usage drive data-collection standards, rather than spending half a year tidying data first. The supporting move

was sending nearly 600 managers, including the entire board, into a closed-door DAMA data-architecture program with unified assessment — nominally training, in substance giving cross-departmental collaboration a shared language.

The case earns its place in this book because it turns Chapter 8's "choice of delivery model" into a question about people. The same report compares three paths: the platform path hands deployment to partners, distributing channels and earning from scale of API calls, at the cost of shallow scenes; the on-site FDE path embeds engineers with the customer, breaking down data silos and burrowing into legal, finance, R&D and the plant floor, with high delivery quality but heavy labor cost and poor scalability; the self-build path is autonomous and turns AI into organizational capability, but depends heavily on one operator who understands both business and technology. **All three paths bottleneck on the same thing: people** — which is why choosing a path matters more than choosing a model.

NocoBase (Chinese: NocoBase) — 14 People, No Headcount Growth, Revenue Doubled: Amplifying a "Thin" Organization [third-party verified]

A 14-person company made a counter-consensus decision: stop hiring. NocoBase builds an open-source no-code development platform; the product started with three people, the commercial edition launched in 2024, and 2025 revenue exceeded RMB 10 million. In the first half of 2026, founder Zhou Yanliang and his team estimated R&D efficiency at roughly three times the previous level — the vast majority of code is written by AI, people barely write it by hand — and the backlog began to clear, removing the need to add engineers. They froze headcount at 14: departures can be replaced, roles can be adjusted, but no new work requires hiring. By the time of the report, 2026 revenue had at least doubled, split evenly between China and overseas[7-94]. Zhou put the restraint plainly: "If we expanded to ten times the people, I wouldn't know what they were supposed to do."

When AI arrived, the first thing questioned was the company itself. After coding tools improved sharply in the second half of 2025, one colleague asked directly whether a no-code layer still had any reason to exist if AI could write software. The team split into two camps and argued for weeks before pulling the discussion back to a more basic question: why do enterprises pay for a software product at all. Their answer did not rest on model capability — how permissions are designed, how data is organized, how processes are orchestrated, how the system evolves over years, how it

connects to existing systems, and who maintains it when something breaks do not disappear because a CRM demo can be generated in minutes. The product roadmap therefore moved upstream: the new version provides infrastructure for AI development, with a delivery flow from requirement to coding, testing and release, plus data sources, data models, permissions, workflows, knowledge bases and a plugin runtime, so that a coding agent can focus only on business requirements.

The organizational change matters more than the efficiency number. R&D time used to be the scarcest resource; now some engineers spend about half their time inside customer projects, support staff fix product issues directly, and the boundary between development and implementation has loosened. Attention has shifted from "how to build it" to "what should we build at all." The company was already thin — distributed, no clock-in, a 20-minute morning meeting, a weekly meeting, everything else asynchronous, no sales team among the 14, and hiring run like courtship, with some candidates talking for six months before joining[7-94].

The case lays the causal chain out clearly: thin is the precondition, AI is the amplifier. In an organization that never had many coordination layers, a several-fold jump in each person's execution capacity propagates straight into the work without an organizational redesign first; in a layered organization, even a threefold per-capita gain has to be spent dismantling transmission losses before it reaches output. This is the same conclusion as 3.1's finding that AI-native firms are smaller, flatter and higher-output per capita, and as the role consolidation in 4.9, reached through a third kind of evidence. Its boundary conditions deserve equal weight: not hiring rests on "no new work requires people," not on treating people as a capacity ceiling; the moment new markets or channels are needed, a 14-person structure comes under immediate pressure.

7.2 International Cases

Klarna — The Most Complete Control Group for AI-Native Transformation

Klarna's AI transformation is the most important retrospective sample in the industry today.

Organizational form: full-time headcount fell from 5,527 in December 2022 to 3,422 in December 2024 (−38%) — the path was a hiring freeze plus natural attrition since 2023 (natural attrition of 15–20% per year), not a one-off mass layoff[7-01] [IPO prospectus data].

On-the-ground practices: externally — an AI customer service built on OpenAI technology launched in February 2024, handling 2.3 million conversations in its first month, about two-thirds[7-07] of total customer service chat volume; internally — AI assistant Kiki has answered more than 250,000 employee questions, used by 85% of employees, and the legal department drafts contracts with ChatGPT Enterprise in about 10 minutes instead of about 1 hour [official claims].

Quantified results: the two yardsticks must be placed side by side. Officially, Klarna claimed the AI customer service would bring $40 million[7-10] in profit improvement in 2024, and by Q3 2025 upgraded the claim to the equivalent of 853 full-time employees and $60 million[7-09] in cumulative savings, with revenue per employee of $1.24 million (3.6 times the 2022 figure); third-party comparisons show that even counting the $60 million in savings, Q3 2025 customer service and operations costs of $50 million were still higher than the $42 million a year earlier — "AI cost reduction" and "rising customer service costs" coexisting.

The controversy and reversal deserve the closest attention: after loudly publicizing "AI replacing 700 customer service agents" in 2024, Bloomberg reported in May 2025 that Klarna was **switching back to human agents**[7-14] — the CEO admitted that going all-in on AI had degraded service quality, and planned to rehire human agents under "Uber-style" flexible employment. CSAT on complex interactions declined markedly and repeat contact rates rose; the overall averages masked a collapse in quality in retention-critical scenarios.

Lesson: AI-native does not equal a one-off mass layoff; purely cost-driven AI replacement has limits; "over-rotation" requires correction. 55% of companies that laid off employees due to AI regret it (Orgvue 2025).

Shopify — Layoffs First, Then AI-Powered Growth

Shopify's layoffs and AI-ification are two separate things, and order matters: 14% layoffs in July 2022, 20%[7-17] in May 2023 (about 2,000 people; officially attributed to selling the logistics business and slowing growth — **not AI replacement; AI-**

ification came after the layoffs). Headcount then stayed flat for multiple consecutive quarters: about 8,300 at the end of 2023 → about 7,600 in 2025, with revenue per employee rising from $1.1 million to $1.52 million[7-24].

April 2025 CEO Tobi Lutke memo[7-19]: employees must first prove "AI can't do this job" before applying for additional headcount; AI usage is included in performance reviews. More than half of merchant interactions with Support are AI-assisted and often fully resolved by AI. Internal productivity platform Shopify OS aggregates business data and recommends the resources and skill configurations a project needs.

Controversy: the memo was read as a "layoff filter" rather than a productivity plan. "Layoffs before AI" versus "AI-driven layoffs" is the key distinction for understanding Shopify.

Anthropic — Eating Its Own Dog Food First

Organizational form: about 2,500 people (2026)[7-26], no mass layoffs — an "AI-native expansion" organization.

On-the-ground practices (official report *Recursive Self-Improvement*): more than 80% of merged production code is written by Claude (May 2026)[7-28]; code output per engineer per quarter is **8x** the 2021–2025 baseline; engineers' roles shifted from "writing code" to "architect + judge" — AI automated code review embedded in CI/CD has intercepted about one-third of downtime-class production bugs in claude.ai's history.

Dissenting voices (also from internal research): the quality of AI-written code was objectively below human-written code until late 2025, reaching only "roughly on par" by mid-2026; employees self-report that 60% of their work uses Claude with 50%[8-40] productivity gains, but 27% of AI-assisted work was "things they wouldn't have done anyway" (exploratory work), and most employees believe only 0–20% of their work can be "fully delegated" to AI; some employees went "about five months without writing code by hand" and worry about skill atrophy and a sense of meaninglessness — the psychological cost of being AI-native is real.

OpenAI — The Highest-Resolution Sample of Whole-Organization Agent-ization

On-the-ground practices (official economic research *How Agents Are Transforming Work*): Codex has become the primary work tool for every department (including legal, finance, and recruiting), accounting for **99.8%**[7-38] of the company's weekly output tokens; the average engineer runs 99% of output tokens through Codex; the heaviest users orchestrate 60+ hours of agent work time in a single day (multi-agent in parallel); 80.6% of sampled users have had Codex execute tasks estimated to require more than 30 minutes of human work.

The most important counter-evidence comes from Fortune (August 2026): OpenAI's own economic research shows **"no measurable correlation between AI usage and revenue per employee"**[7-39] — the spread of AI-native tools does not guarantee that productivity will be realized. Even the maker of AI tools itself cannot produce evidence that "the more you use, the more you earn."

Latest development (Wired, August 2026): OpenAI appointed Codex lead Thibault Sottiaux to take over the entire ChatGPT product line[8-70]; ChatGPT will transform into a "personalized agent super-app" driven by Codex at its core (a 40-person team, folded into ChatGPT within weeks). Its self-attribution is worth noting: the earlier failures of Operator/ChatGPT Agent were attributed to "too early, models unreliable" plus users not knowing what to do with agents; the new strategy is small, fast releases — "you can't do a big splash and then get it wrong." **Even the most aggressive agent-ization sample is hedging against the uncertainty of agent products with small, fast releases.**

Notion — A Thousand People, No Layoffs, AI as the Second Growth Curve

About 1,000 people, no layoff record. ARR surpassed $600 million in December 2025, **roughly half of it from AI products**[7-41]; paid AI add-on penetration rose from 10–20% in 2024 to over 50% by September 2025. Notion AI[7-42] launched in November 2022 (about two weeks before ChatGPT's public launch). Its path is product-driven rather than organization-slimming — driving paid penetration through AI features rather than through layoffs.

Cursor — King of Revenue per Employee

About 300 people: ARR $100 million in January 2025 → $500 million in June → $1 billion[7-45] in November → about $4 billion[7-48] by June 2026; revenue per employee of $3–13 million. In June 2026, SpaceX announced an all-stock acquisition at a $60 billion valuation (completed in August, folded into SpaceXAI).

Controversy: in April 2025, AI customer service program "Sam" fabricated and executed a nonexistent login policy, causing users to cancel their subscriptions — a textbook incident of "an AI agent acting beyond its authority."

Duolingo — Zero Full-Time Layoffs and 11x Content Production

In January 2024, Duolingo cut about 10% of its contractors (outsourced translation and content production)[7-50] and switched to generative AI for content; the CEO said the company has **never laid off a single full-time employee** since its founding in 2009. Content production: 1,800 course skills per quarter in 2024 → 7,100 in 2025 → 20,500 in Q1 2026 alone — about 11x[7-55] in two years, which the company explicitly says "wouldn't have been possible without AI."

Controversy: the contractor cuts triggered a PR crisis (large-scale TikTok/Reddit discussion of "replacing workers with AI")[7-56]; after the April 2025 AI-first memo sparked layoff speculation, the CEO publicly clarified, and in May 2026 the memo was reported to have been retracted[7-53]. **The first cut of AI replacement lands on the most vulnerable flexible workers — a pattern that holds across cases.**

Airbnb — 60% of Code Co-Written by AI

No AI-related layoffs; Q1 2026 earnings call: **60% of engineer-produced code is co-written with AI**[7-57] (Google claims 30%+, Microsoft up to 30%[7-61] — Airbnb is at the high end of public claims); the AI customer service bot handled 40% of customer service tickets without human escalation in Q1 2026 (from about 33% in early 2025), with plans to expand to 50+ languages.

Dissenting voice (the CEO's own admission): Chesky publicly acknowledged that "no one has truly solved the AI travel problem," listing the chatbot's four major flaws (text overload, inability to operate directly, difficulty comparing, and mismatch in multi-person booking scenarios).

Basis / Clay / Exa — Three Ways to Weave Agents into Daily Work [official claims]

OpenAI's Enterprise Signals quantifies the gap: **frontier firms — the top 10% by usage — now generate 8.3x as many output tokens per active user as typical firms, up from 2.6x in January**[7-74]. The same material describes three small companies whose approaches cover the three stages of agent adoption[7-74]: Basis (which builds agents for accounting firms) demonstrates the onboarding process once, then turns it into an onboarding skill (a clear trigger, known steps, tool access, and a definition of done), cutting first-day onboarding from two hours to 30 minutes and removing dependence on one person's availability; Clay gives every account a persistent workspace and a dedicated subagent that reviews primary sources overnight, with a coordinating agent turning those updates into a short morning list of priority moves, saving one seller about an hour of inbox triage each night; and Exa Labs turns the path from discovering an integration opportunity to shipping it into a defined Codex workflow — monitoring for high-priority opportunities, gathering context, opening pull requests, running tests, and preparing weekly updates — while **people still decide which opportunities matter and what the company should commit to**. Together they make one point: **teach an agent a stable process, give it persistent context, let it carry an opportunity into tested action — and make improvement part of the workflow.**

WEF *Organizational Transformation in the Age of AI* — The Enterprise Samples [third-party verified]

Based on a survey of more than 450 executives, this white paper converges leading practices into five areas[1-38]. On customer experience, Ford's AI decision engine dynamically adjusts audiences and content across multi-wave campaigns based on real-time feedback, reaching more than 300,000 customers in three weeks with a 26% conversion lift; Rabobank's unified customer decision center delivers more than 1.5 billion personalized interactions a year, quadrupling click-through rates, raising customer lifetime value by 4.7%, and cutting service costs by 2.4%; Visa's intelligent commerce system lets consumers set autonomous purchasing permissions and lets AI agents complete authorized transactions. On operations, Lenovo embedded iChain AI agents in the core of its global supply chain to monitor demand, supplier constraints, and freight flows and optimize shipments dynamically, **raising shipping accuracy by 30%**; Siemens lets frontline workers flag design quality issues

in natural language, with AI aggregating and routing them to the right teams. On R&D, Merck's AI virtual platform screens more than 60 billion chemical targets within minutes, cutting the time and cost of candidate-molecule screening by up to 70%; Lundbeck built a headache-disease knowledge graph integrating 54 million electronic medical records, speeding target identification by 80%; and Ignota Labs acquires drug candidates abandoned over safety concerns, uses AI to identify the toxicity mechanism, and redesigns them, returning compounds to clinical trials in under two years and under $1 million, versus 7–8 years and over $10 million traditionally[1-38]. **The organizational implication: AI-native is not placing AI in some innovation unit — it is embedding it in the default paths of core systems such as customer interaction, supply chain, and R&D.**

Kavak — Generating a Dedicated Agent for Every Customer

Kavak, the Latin American used-car platform, made a company-level bet on "running the company with agents," and its architectural choice runs opposite to most enterprises: **it generates one agent per customer, each with its own micro-VM**, rather than one agent per job or task — on the reasoning that an agent is essentially a "context isolation container"[7-80]. The agent remembers years of interaction between the customer and the company (which pages they browsed, what call they made two years ago), sets long-term goals to maximize that customer's lifetime value and cross-sell across product lines, and sleeps after setting an alarm for its next task.

The operating data makes the scale of this model concrete: **about 96% of customer interactions are handled by agents with no human involvement, and about 95% of transactions are completed entirely by agents** (only physical steps such as in-person vehicle handover keep people in the loop); roughly 100,000 to 200,000 agent instances are created per day, some working three minutes, some eight hours, some three days; and of the 10 million customers in the database, many already have an assigned agent[7-80]. The business results carry more organizational meaning: capabilities that once required 15 roles and 15 teams — financing specialists, car advisors, vehicle-acquisition experts, insurance specialists — were **merged into a single sales agent**, lifting customer satisfaction/NPS to roughly three times the previous level; the agent's conversion rate started at 50% above the human team and is now more than 2.1x the human team; and auto-loan approval dropped from the industry-typical two months or more to about three minutes. Two methodological points deserve separate note: **evals are the brake** — engineering

the evaluation system costs about as much as building the agent, and "how fast you can run depends on the quality of the evals"; and the team measures only conversion and customer value, not vanity KPIs such as call counts or minutes. When the agent hits a wall, it calls an "I need help" API whose other end is a human — **humans work for the agents, and that loop simultaneously produces training data**. Kavak also piloted an "AI CEO" in Cuernavaca, Mexico, raising that city's profit 50% in six weeks (against a target of doubling, which was not met).

Calendly / SmartHR / LINE Yahoo / Plaid / Safie — Five Field Samples of Weaving Agents into Daily Processes [third-party verified]

Chapter 5 described how four companies put agents into the engineering loop; this section draws out the organizational meaning of three of them and adds two Japanese companies. What they share is that **the agent was not "a new tool for engineers" but a member woven into a team with roles, handoffs and gates.**

Calendly: the loop persists in Jira, GitHub, CI and repository instructions rather than living in a disposable chat window; the IAM team produced 64 PRs in about a week and a half (37 merged), and an internal tool let a designer and a product manager deliver code for the first time. They framed the bottleneck shift as moving from writing code to alignment to judgment — "handing a vague ticket to a very fast agent only gets you a wrong result faster"[7-87].

SmartHR: the stated goal is "AI-native development" — a development system optimal for AI rather than simply getting people to use AI tools; concretely, the parts formerly conveyed orally by senior engineers (how specs are written, how reviews are read, how verification is done) were turned into processes an agent can execute[7-88]. The same company left a full track record of team rollout: start from one experimental squad, let people see that this really is faster and less painful, then spread layer by layer as it is reproduced, until teams share one environment[7-89]. **The organizational implication: the smallest unit of spread is not "training" but "reproducible speed."**

LINE Yahoo: Claude Code × MCP automates PR review *preparation* — an agent first gathers scattered context (intent of the change, linked issues, relevant history) into review material, then hands it to a human to judge. What is saved is preparation time, not review time: reportedly about six hours per team per week[7-90]. **The**

organizational value of this kind of change is that it leaves review authority untouched and only frees people from gathering material — automate the floor, preserve the ceiling.

Plaid: all agent configuration is committed to the repository alongside human documentation, and a five-person team moved from roughly 150 to roughly 600 PRs a month; their summary is that "the era of reading code is not over, but what you read has changed"[7-91].

Safie: this security-technology company did not start with tool selection. It first defined five strategic axes (turning "what we do with AI" into a strategic proposition), then openly recruited about 20 willing employees into a cross-departmental promotion team and spread outward[7-92]. **Strategic axes first, a volunteer squad second, tools last — this order matches all four cases above, and matches Chapter 8's requirement that Stage 0 is a decision.**

Cybozu (Japanese: サイボウズ) — Writing the Work Down as Agent Skills: Three Starting Moves for Team-Level Collaboration [third-party verified]

This Japanese SaaS company's team reduced "working with agents" to three executable moves. Tateyama, an engineering manager in kintone's generative-AI team, documented their starting method: first verbalize the work and define it as Agent Skills, then make the skills a team-shareable asset, and finally prepare an environment where failure is affordable. The order matters — the starting point is not "build an impressive AI system" but "get the shape of the work right and reduce it to steps that can be delegated to AI"[7-95].

Delegate whole pieces, not fragments. Their judgment runs against common practice: hand an entire job to the agent and keep only the final judgment and approval for people; passing context back and forth repeatedly between human and AI is slower than doing it yourself. Whole-piece delegation has a side effect — it forces the team to write the entire procedure down as knowledge and, in passing, removes dependence on any one person. In form, an Agent Skill is essentially a natural-language prompt written in Markdown; no programming skill is required, so non-engineers can write one, and including concrete bash commands and MCP tool references raises the agent's success rate noticeably.

The sharing mechanism decides whether knowledge actually accumulates. They keep Agent Skills in a Git repository and let the team subscribe through the Claude Code Marketplace with a single command — a barrier low enough that "this was useful, let me add it" becomes routine. Once that mechanism existed, members began contributing skills on their own, tacit knowledge turned into something the whole team could read, and newcomers could see from the skill files how the team works. The third move is the safety net: automated smoke tests after deployment, SLOs and alerts defined with CloudWatch Application Signals, and a Dev → Staging → Prod pipeline so the agent's changes are caught before users are affected. **The goal is not "make sure AI never fails" but "make sure AI's failures are affordable"** — the same principle as the guardrails in 5.7 and the pilot design in Chapter 8.

They do not overclaim. The post lists two unresolved problems honestly: where documentation should live (the place that is easy for humans to write and the place that is easy for agents to read do not coincide, and scattered sources make it unclear which version is authoritative), and remote execution environments beyond the code repository (real work needs internal systems and cloud services, and there is no standard answer yet for letting agents run autonomously and securely). A Gartner forecast they cite supplies the wider backdrop: by 2030, 80% of organizations will shift from large engineering teams to smaller, more maneuverable AI-augmented teams.

7.3 Cross-Case Comparison: Seven Patterns

1. **Three organizational paths coexist**: downsizing (Klarna), expansion (OpenAI/Anthropic), steady-state leverage (Shopify/Duolingo/Airbnb) — there is no single answer;
2. **The "first cut" of AI replacement lands on flexible labor**: Duolingo's contractors, Klarna's outsourced customer service — full-time layoffs are actually rare;
3. **Evaluation systems are being reshaped by AI**: Shopify (AI in performance reviews), Duolingo (AI-first memo);
4. **The tension between claims and verifiable data is the most valuable part of this book**: Klarna ($60 million in savings coexisting with rising customer service costs), OpenAI (its own research: no correlation between AI

usage and revenue per employee), Anthropic (AI code quality was once below human quality) — the promotional surface and the factual surface must be placed side by side;

5. **Reversals and backtracking are the norm**: Klarna switching back to human agents, Duolingo retracting its memo, Cursor's Sam incident — no company's AI-native transformation is a straight line;
6. **Extremes in revenue per employee**: Cursor (300 people, $4 billion ARR) is the ceiling sample for small teams; Klarna ($1.24 million per employee) is the sample for large-organization transformation — the shared financial trait of AI-native organizations is per-capita output well above peers.
7. **The unit of configuration is sinking.** From "AI per process" (banks' agent platforms and scenario lists), to "a digital employee per post" (CITIC Securities' "one digital employee per role, one assistant per person"; WeBank managing digital employees as posts), to "an agent per individual or customer" (Kavak instantiating one agent per customer). **The further it sinks, the less the organization needs to rewrite the systems-integration list — and the more it must rewrite how tasks are divided, who holds the context, and who signs for the result.**

Chapter 8 Building Your AI-Native Organization: An Action Playbook

The previous chapters answered "what" and "why"; this chapter answers "how." We integrate the transformation frameworks of Anthropic, Rubrik, BCG, McKinsey, and Accenture with Chinese practical methodology, converging into an executable four-stage roadmap.

> **Overall principle**: first reduce organizational friction (the denominator), then multiply talent density × AI leverage (the numerator); first rebuild workflows, then talk about automation; start with one workflow rather than restructuring the whole company at once.

Stage 0: Decision and Preparation (2–4 Weeks)

Goal: answer "why are we transforming, who leads it, where is the floor" — no code, no tools purchased.

#	Key Actions
0.1	**Executives hands-on**: CXOs trial AI tools in at least 3 core business scenarios to build first-hand understanding (Accenture research found that only 12% of leaders consider themselves able to iterate quickly with limited information — hands-on use is the only cure for this)
0.2	**Form an AI steering committee** (business line leads + CFO + CTO + HR), clarifying a responsibility structure of "business-led, technology-supported, finance-accounted"
0.3	**Define the value standard**: only four categories of quantifiable value are recognized (revenue growth / cost reduction / efficiency gains / quality improvement); projects without a business owner and quantifiable metrics are not approved
0.4	**Data and compliance check-up**: AI-ready data inventory, Shadow AI audit (tool list + exposure surface), vendor lock-in assessment (multi-model routing contingency)

Common mistakes: outsourcing Stage 0 to the IT/data department to run alone (technology charging ahead solo); treating "buying Copilot" as the transformation itself; skipping the data inventory and going straight to pilots.

Stage 1: Assessment and Selection (4–8 Weeks)

Goal: identify "few but excellent" high-value workflows, decide Build vs Buy, and establish measurement baselines.

#	Key Actions
1.1	**Workflow inventory**: list all workflows per business line, mark "frequency × pain intensity × value measurability," and screen **3–5** highest-value workflows per business line (the Rubrik method)
1.2	**Prioritization**: prioritize a single value goal (McKinsey: projects focused on a single goal succeed at 3.2x the rate of broad-goal projects); prioritize back-office / mid-office functions (MIT: compliance and operations have the highest success rates)
1.3	**Build vs Buy**: MIT evidence shows that external procurement/partnership success rates are about 2x those of internal build — default to Buy/partnership, and build in-house only for data sovereignty or deep-customization scenarios
1.4	**Baseline measurement**: record current cost/cycle/quality numbers for each candidate workflow (with the CFO involved)
1.5	**Governance up front**: data permission matrix, output auditing, multi-model routing, and guardrails built at the design stage rather than after launch

Common mistakes: launching dozens of pilots at once (pilot proliferation → locally optimal, globally worst); choosing scenarios that "leaders think are cool" rather than "business pain points"; governance after the fact.

Stage 2: Pilot (30–90 Days)

Goal: validate real value on 5–15% of traffic / the smallest business unit, forming a replicable model.

#	Key Actions
2.1	

#	Key Actions
	30–60 day value pilot: single pain point, short cycle, preset metrics (adoption / efficiency / quality / satisfaction, four dimensions); human fallback during the pilot, but **record the fallback workload** — it is the real cost of productionization
2.2	**Small-traffic ramp-up**: start with 5–15% of traffic, monitor daily, tune quickly; small-step pilots succeed at about 4x the rate of full rollouts
2.3	**Human-AI division of labor design**: clarify the three-layer routing of "AI end-to-end / AI-assisted human / human-led" (Klarna's hybrid model: 60–70% / 20–25% / 5–15%); high-value complex interactions default to human-led
2.4	**Design for production from day one**: shared context layer, standardized action layer, governance embedded in the system — rather than "bolting on productionization after pilot success" (these are the three decisions of the 5% who succeed)
2.5	**Value accounting**: after launch, account using real business data (CFO-led validation succeeds at a 76% rate vs 53% for technology departments vs 32% for business departments)

Common mistakes: pilots that perform through "expert fine-tuning + human fallback" (such a pilot is not a product, it is a performance); pilot success without value accounting; human fallback workload hidden during the pilot and costs underestimated. **A subtle one: letting the agent change production code and tests at the same time — the tests lose their evidentiary power (the agent can redefine "correct" in the same breath); production and tests must be changed in separate phases** (a practical lesson from Yadda 3.0).

A product manager's 8-week permission ladder [third-party / hands-on debrief]: one product manager spent 8 weeks and about 2,200 yuan a month moving an operations team from skepticism to dependence. The three-level leap is a permission design, not a feature design: AI Intern (read-only queries, opened to everyone to build trust) → AI Advisor (recommendation-only, piloted with 10–15 people to validate value) → AI Expert (execution-capable, opened only after maturity and kept under human confirmation)[8-84]; three safeguards accompany it — device whitelists, daily quota limits, and a circuit breaker after three consecutive failures; and the trade-off between "automatic execution vs. human confirmation" must be confirmed in writing by the business unit, not decided unilaterally by the technology

team. Outcome metrics from the debrief: recommendation adoption above 60%; a single query dropping from 3 minutes to 8 seconds; and on-site troubleshooting roughly tripling problem-resolution speed. The essence of the permission ladder is trading trust for autonomy — every level of permission is unlocked by the adoption data of the level below.

Stage 3: Scale (3–12 Months)

Goal: replicate the validated model to the remaining scenarios in the same business line, other business lines, and other regions; accompany it with organizational change.

#	Key Actions
3.1	**Standardized reusable components**: models, data rules, processes, permissions, and operations all modularized (portable = scalable)
3.2	**Process redesign before tool stacking**: delete redundant steps, merge duplicate tasks, reset the human-AI division of labor; companies that reengineer processes convert about 5x more AI value than those doing patchwork fixes
3.3	**Systematic training**: structured training (rather than issuing licenses); include AI usage in reviews and promotions; leaders lead by example
3.4	**Incentives and trust**: clearly communicate that "AI liberates employees rather than replacing them" (see Transn's Energy Gold); enablement strategies can raise retention by about 32%
3.5	**Organizational design keeps pace**: as the number of agents rises, establish agent operations / admission / accountability roles; monitor agent behavior, and ensure rollback and auditability (98% of enterprises have experienced disruptive events related to AI agents)
3.6	**Cost governance**: monitor on a "cost per resolved case / full-cycle cost" basis (rather than per-inference cost); cost is the #1 reason 40%+ of agentic projects get cancelled
3.7	**Trust-building and observability**: delegate authority in tiers using a "concentric-circle" model — inner circle: agents self-verify and auto-merge; middle circle: pre-annotated human review with observability context; outer circle: deep human intervention. Detect agent drift via tool-call trajectories (e.g., 15 calls without

#	Key Actions
	converging = stuck) and SLO burn-rate alerts; black-box tools that expose no telemetry should be vetoed in vendor selection; bounded tasks with frequent control hand-backs are the best practice (Honeycomb)

Common mistakes: scaling tools without scaling processes (technology does addition while processes stand still); no supporting training and incentives (the cause of 64% of Copilot licenses sitting idle); going full release the moment promotion starts.

Stage 4: Institutionalize (12–24 Months, Ongoing)

Goal: make AI part of the organization's operating system — governance institutionalized, skills assetized, innovation mechanized.

#	Key Actions
4.1	**Institutionalize the kill mechanism**: projects that fail value metrics, cannot scale, or are only fit for demos are forcibly stopped (sunk cost obsession is an accomplice to the pilot trap)
4.2	**Full-cycle value disclosure**: pilot → production → post-evaluation → formal disclosure; AI value enters management analysis (putting an end to the "efficiency myth")
4.3	**Skills as assets**: structure senior employees' tacit knowledge (SOPs / cases / data annotation) to prevent the double kill of "skills gap + tacit knowledge loss"; design "AI sparring-partner" learning paths to counter skill atrophy
4.4	**Mechanize innovation**: expand from the single goal of "cost reduction and efficiency gains" to BCG's Reshape/Invent (reshaping business models with AI, inventing new businesses), avoiding "efficiency thinking locking out innovation space"
4.5	**Dynamic reassessment**: model capabilities leap every 6–12 months (Anthropic internally: agents' autonomous actions went from 10 to 20), so the human-AI division of labor boundary needs regular renegotiation

Common mistakes: treating "launch" as the finish line (no post-evaluation, no kill switch); permanently locking AI into the efficiency-tool layer; ignoring the division-of-labor boundary drift caused by model iteration.

Supplement: BCG's Three Value Plays and Accenture's Three Leadership Principles

BCG: Deploy / Reshape / Invent. Deploy (apply off-the-shelf AI to existing processes — fast, but with shallow moats) → Reshape (redesign how work and business models operate — the main force in the medium term) → Invent (create entirely new AI-native businesses — the highest long-term value). **The three plays are not a multiple-choice question; they are a progressive combination.**

Accenture: curiosity / courage / connection. Curiosity — test AI yourself, hands-on, rather than delegating to the technology team; Courage — act with incomplete information, dare to decide "where not to deploy AI," and set up governance in advance; Connection — listen first (to employee anxiety), then use narrative to connect change with meaning, and build cross-functional alliances among executives early.

Common Mistakes Quick-Reference Table (Across the Full Cycle)

#	Mistake	Counter-Evidence	Right Approach
1	Buying tools = transformation	64% of Copilot licenses idle	Training + process redesign + incentives, the three-piece set
2	Layoffs first = cost reduction	Klarna's reversal, 55% regret rate	Augmentative collaboration (AI empowers people)
3	The more pilots the better	Pilot proliferation → globally worst	3–5 high-value workflows per business line
4	Pilots propped up by manual patches	Pilot succeeds, production collapses	Design for production: context / action layer / governance
5	Only look at inference cost	Cost per resolved case can exceed offshore labor	Full-cycle cost basis + CFO accounting
6	Run AI on ungoverned data	60% of projects abandoned over data	Stage 0 data check-up first
7	Single-vendor lock-in		

#	Mistake	Counter-Evidence	Right Approach
		Switching costs 19–34%, price increases 20–40%	Multi-model routing + portable context
8	Employee fear unaddressed	64% don't trust AI agents, nearly half anxious	Leaders listen + narrative + enablement strategy
9	No kill mechanism	Sunk costs forced through, waste amplified	Institutionalize the value gate
10	Only Deploy, no Reshape/Invent	Efficiency thinking locks out innovation space	Advance the three value plays in combination

Three Lightweight Principles for Small and Mid-Sized Teams

If you are a small team (10–50 people), you don't need the full four stages:

1. **Find the "AI nodes"**: not every role suits AI adoption. Look for steps in the business that are **high-frequency, repetitive, and still require a degree of judgment**; get three to five key nodes working first so the team tastes success — the team itself will go find the next node;
2. **Give the front line tool choice**: give everyone tool choice and an AI tool budget; good practices spread naturally, which is more effective than top-down promotion;
3. **Evaluation criteria must change**: from input to output, from process to results — without changing evaluation, AI adoption is empty talk.

Small Teams Delivering Enterprise AI Services: From First Deal to Ongoing Operation

A small team that sells AI services to other enterprises can treat its own delivery as a "mini AI-native organization" rehearsal — a 3–5 person team running an enterprise AI first deal from lead to renewal is itself a playbook worth copying.

Sell results, not features. Don't write "integrate LLM + knowledge base" in the project charter; write the deliverable boundary: which type of work, which people, which metric goes down. The customer is not buying "which large model was connected" but a piece of work that used to require repeated human effort, done faster, more reliably, or cheaper under controlled risk.

3–5 people cover four responsibility areas — headcount is not the point; someone owning each responsibility is. Business and delivery lead (client screening, requirement interviews, scope confirmation, translating vague needs into executable, acceptable tasks); AI/full-stack engineering lead (models, retrieval, agents, workflows, deployment); business analysis and adoption lead (organizing process knowledge and rules, building test questions, training, collecting real user feedback — the role most often cut, and cutting it means the system runs but nobody uses it); and security, data, and domain expertise (can be part-time or via partners, but personnel, finance, healthcare, legal, production-control, and sensitive-data decisions must be made by professionals).

Acquisition: don't look for customers who "want to do AI." The five signals of a qualified lead: high-frequency repetitive work that has become a burden; a business owner attends (not just IT); pilot-able data and materials exist; real users are willing to test; and there is an initial definition of success with willingness to commit resources (the most important one).

A four-tier service ladder — never start with a free POC. A free POC means unlimited scope creep with no budget, no acceptance, and no end date. Paid diagnosis (a half-day to one-day process diagnosis the customer keeps even if they don't proceed) → controlled pilot (validate only the key assumptions: one product line, one department, one set of approved documents) → production deployment (add permissions, logging, monitoring, integration, training, operations) → ongoing operation (content updates, evaluation regression, cost optimization, incident handling, new scenarios).

Freeze the baseline before promising savings. Without a baseline, promising cost reduction is unprovable. Four baselines: business (process steps / volume / duration / error rate / satisfaction), data (volume / format / version identification / sensitivity level / content owner), technical (environment / permissions / interfaces / logging / model licensing), and evaluation (a real question set plus current human

results). Ship the first "evaluable version" in two weeks rather than a complete one, and re-run the fixed test set on every model, chunking, prompt, or workflow change — an AI project without an evaluation set is judged by demo luck.

Three tables keep things from running out of control. Weekly report (surfaces blockers and decisions, not effort), risk register, and change request log (verbal "just add it while you're at it" never enters development). Agree acceptance metrics before development starts; every metric answers four questions: what is measured, with what data, by whom, and what counts as passing. Put AI inside the employee's existing work entrance (Feishu, WeCom, CRM, ticketing) rather than asking them to open another website they will forget.

Turn one project into a repeatable service. Each project accumulates five asset classes: an industry problem bank, diagnosis and proposal templates, technical components, a desensitized acceptance dataset, and an operations manual — forming a "delivery foundation" that can be adapted to new customers quickly. Don't wait until contract expiry to talk renewal — monthly reviews report which jobs users use AI in, which questions still fail, whether manual handling has decreased, and how business metrics moved, not call counts. When sustained value holds, renewal is a natural result.

The ten most common traps for small teams are worth pinning on the wall: accepting any customer (scattered industries → nothing reusable); free POCs without end conditions; promising outcomes by model capability; pre-sales promises never written into the SOW; talking only to IT, not the business owner; promising savings without a baseline; substituting demo questions for a real test set; handing every problem to the prompt (data, permission, and process problems dressed up as prompt problems); not daring to reject scope changes; and doing no asset accumulation after delivery.

Prerequisites for Scale: Registration, Audit, and Accountability

In pushing AI from pilots to the whole organization, the hardest step is not technology selection but answering "who is using it, where, and who is accountable if something goes wrong." Three approaches from different systems point the same way.

Register first. Before expanding agent use across the public sector, Singapore's Government Technology Agency (GovTech) developed a registry to track public officials' use of AI agents, as part of its AI Assistant Desk suite, so that scaling would remain "manageable and auditable"[8-111]. The lesson is about sequence: **before letting thousands of employees each use an agent, bring them into a unified inventory — who is using what, where, and within which boundaries.** It follows the same governance logic as enterprises' "one unified foundation, a capped number of base models, and vendors required to expose APIs."

Responsibility cannot be transferred. In September 2026, US Federal Trade Commission Chairman Andrew Ferguson said he would resist describing AI agents as autonomous actors that "break loose" with "wills and desires of their own": if someone tells a tool to do something and the tool does it, the question is not "what do we do about the tool" — the developers and deployers who issued the instructions are the responsible parties[8-112]. He also noted that repeated post-hoc audits showed systems described as "beyond human control" were in fact carrying out instructions they had been given. **That means organizations designing automation must preserve not only approval buttons but complete records of instructions and traces — because responsibility cannot be transferred out along with "AI autonomy."**

Returns have to be measurable. Gartner's data offers a sober baseline: only 41% of agent deployments cross into positive ROI within 12 months, and 19% never pay back at all[8-113]. This is not an argument against doing the work, but it does determine sequencing — start with measurable scenarios (review acceleration, customer-service assistance, engineering work orders) and leave high-risk, high-value redesigns until an evaluation framework exists. The corresponding organizational move is to express "losses avoided," "capacity released," and "risks surfaced earlier" in comparable metrics; otherwise budgets keep flowing to shallow scenarios that are easy to see.

Write the policy down, including when not to use it. Oxide Computer published its internal LLM policy as a public RFD, listing five values in priority order — responsibility, rigor, empathy, teamwork, and urgency: responsibility for artifacts rests with the human who uses them, with human judgment firmly in the loop; used carefully, LLMs sharpen thinking, and used carelessly they replace crisp thinking with generated flotsam[8-114]. One point in particular is worth copying in Chinese organizations: **disclosure is not always the same as honesty — in some**

contexts, volunteering that an LLM was used can be read as distancing oneself from responsibility for the content, eroding the trust that teamwork depends on.

Choosing a Delivery Model: Three Forms of FDE and How to Design the Exit

The previous sections answered "how do we do this ourselves." But most enterprises do not build from scratch — they buy — which makes "how do we choose a delivery model" a decision variable as important as organizational design, with a failure rate just as sobering.

In September 2026 Gartner offered a jarring prediction: by 2028, 70% of enterprises will abandon agentic AI built by vendor forward-deployed engineering (FDE), because costs spiral and the enterprise cannot evolve it on its own; the failure is structural before it is technical — **"FDE engagements often fail structurally before they fail technically"**[8-122]. Three prescriptions can be copied straight into a procurement review. **Before signing**: use FDE only for problems that need deep product knowledge, fast adaptation or deep integration; name an executive sponsor accountable for business results rather than implementation budget; and write deliverables, knowledge transfer, IP ownership and exit responsibility into the contract. **During delivery**: keep the pace at a level the internal team can follow — embed FDE alongside internal domain experts and end users, and use each increment to define the balance of decision rights, autonomy and human oversight. **On exit**: execute the plan agreed at the start; the most common failure mode is exactly the postponement that follows "the internal team isn't ready," which leaves the enterprise with neither the capability nor the money. Acceptance criteria therefore have to be rewritten: success is not implementation completion but **whether the enterprise can manage, optimize and scale it itself — including adjusting the human-machine decision model as processes and risks change**. The same forecast adds two useful warning numbers: fewer than 20% of FDE engagements will convert clients' recurring needs into vendor core product capability by 2028, and "FDE washing" — repackaging ordinary consulting as FDE — is spreading.

The three paths are best contrasted using Chinese enterprises: the platform path hands deployment to partners, distributing channels and earning from scale of API calls, at the cost of shallow scenes; the on-site path embeds engineers with the

customer, breaking down data silos and burrowing into legal, finance, R&D and the plant floor, with high delivery quality but heavy labor cost and poor scalability; the self-build path is autonomous and turns AI into organizational capability, but depends heavily on one operator who understands both business and technology (SANY Heavy Industry's GPO mechanism is the sample of this path)[7-93]. **Choosing a path matters more than choosing a model — and all three bottleneck on the same thing: people.**

In institutional design, making experiments cheap pays off earlier than making them correct. One Japanese payments company's approach is worth copying: an "AI trial budget" that sits outside departmental budgets so new ideas can be validated quickly outside normal approval; virtual cards with per-service and per-person limits settled centrally by finance; and usage limits mapped to data-protection tiers plus settings that prevent information flowing into model training — all in place beforehand, which in turn became the key to fast approvals (the same batch of practice includes a side note: one company's Claude Code, with its built-in ripgrep, reached 80-90% of expectations on a four-million-line monorepo "without elaborately written rules")[8-124].

Pacing, finally, needs an honest time base. One cloud vendor's four phases — drawn from customers in automotive manufacturing, hotels, pharmaceutical retail and logistics — are knowledge cold start → workflow orchestration → multi-agent collaboration → governance and operations, with reference timelines of one to two weeks for a simple FAQ agent, four to six weeks for multi-scenario, and eight to twelve weeks for a multi-agent system; and **knowledge cold start typically consumes 40-60% of total deployment time**[8-125]. The value of that ratio is not the ratio itself but that it translates a promise about "launch time" into a question about "how much time are you willing to spend on data and knowledge" — any plan that puts that ratio at 10% deserves more questions.

One last note from a front-line consultant applies equally to self-build and outsourcing: only the speed of routine implementation changes (admin CRUD work can drop to under a third of its former time), along with the quality of juniors' style, the review lens (from naming and style to whether the design can extend, whether boundaries are reasonable, whether the business logic is explained correctly) and hiring standards (from "write this code" to "review this AI-written code"). **What does not change is that architecture decisions still need humans, inter-team communication cost does not fall and in fact becomes more visible, technical**

debt does not resolve itself and may accumulate faster, and security review matters more — he saw AI-generated code containing SQL injection almost slip through review because it "looked tidy"[8-126]. Designing the rules for what is handed to AI and what must stay human matters far more than tool selection, and he offers one ownership principle usable as-is: **ownership of AI output belongs to the person who issued the task.**

The Core Judgment of This Chapter

Transformation doesn't need a perfect start; it needs the right first step. Pick one workflow, one owner, one quantifiable outcome, design for production, iterate for 90 days — then let success speak for itself. In Chapter 9, we will see what those who didn't do this paid for it.

Chapter 9: Challenges, Risks, and the Future

9.1 Failure Cases: Transformations Done Wrong, and Ones Never Got Around To

Klarna's reversal (detailed in Chapter 7) is the most complete sample of a "transformation done wrong": AI customer service loudly replaced 700 people → quality collapsed in complex interactions → quietly switched back to human agents. Five lessons:

1. **Blind spots in the business case**: only labor-cost savings were counted; revenue loss, repeat-contact costs, and the "cancellation cost" (after publicly announcing that the work was automated, strong candidates no longer wanted to join) were not;
2. **Experiential knowledge cannot be rebuilt**: the tacit knowledge senior agents used to handle edge cases disappeared permanently when the teams were cut;
3. **Metric choice determines success or failure**: overall averages masked the quality collapse in retention-critical scenarios;
4. **A viable hybrid model**: three-layer routing (60–70% / 20–25% / 5–15%);
5. **Industry-wide contagion**: fintech, healthcare support, and insurance claims all show the same pattern of "full automation → quality degradation → quietly backfilling with humans."

Samsung's Shadow AI incident: in April 2023, three incidents in 20 days of employees uploading sensitive information (semiconductor equipment measurement data, source code) to ChatGPT led Samsung to ban generative AI outright and build its own alternative. **A "throw-the-baby-out-with-the-bathwater" ban sets the transformation back; the right posture is to provide a managed, enterprise-grade AI environment, offsetting Shadow AI with alternatives rather than bans.**

Microsoft Copilot's licensing dilemma: about 64% of enterprise Copilot licenses sit unused, and only 3.4% of M365 customers pay for advanced AI features; 72% of IT leaders say employees struggle to integrate Copilot into their daily

workflows. **Between the purchase decision (made by the CIO) and the usage decision (made by frontline employees) stand three gates of organizational inertia — whether processes have been redesigned, whether leaders model the behavior, and whether performance reviews are tied to it: procurement ≠ adoption, and licenses ≠ value.**

Chegg's cost of not transforming: in May 2023 it admitted that ChatGPT had taken its student users; the stock plunged about 50% in a single day, followed by multiple rounds of layoffs, with the stock cumulatively down about 99% from its peak. Chegg's problem was not "doing the transformation wrong" but "not getting to the transformation in time" — its core business model (paid homework answers) was zeroed out directly by free LLMs. **There is a time window for building an AI-native organization.**

9.2 Six Root Causes of Failure

Root cause	Representative case / data	Characteristic signals
Environment mismatch (the enterprise was never designed for AI)	Pilots succeed, production always collapses; MIT 95%	Pilots held together by manual patching; collapse in production
Replacement mindset (layoffs first)	Klarna; "replacement-style automation"	Satisfaction/retention deteriorate; quietly rehiring
Procurement ≠ adoption (organizational inertia)	Copilot 64% of licenses idle	License costs sunk, low activity
Missing data and governance foundation	60% of projects abandoned over data; Samsung leak	Shadow AI rampant; projects blocked by data
No value accounting	Only demos and usage rates, no P&L numbers	"Pilot boom, value void"
Organizational runaway (the AI-era product-bloat disease)	Cloudflare's fragmented storage/ compute/agent product lines, "dream it→vibe it→ship it"	Product count up, developer experience down, platform value diluted

The Seven Pitfalls: A Failure Checklist from a Critical Perspective

The product manager orangeburn, writing from the realities of China's client–vendor relationship, offers a seven-pitfall checklist for legacy-enterprise AI transformation that mirrors the six root causes above: treating AI transformation as a "decision problem" (asking an "expert" for a plan is like asking the blind for directions — first ask yourself why you are transforming); treating an AI strategy as the transformation itself (strategy is made, not thought up; the strategy document is obsolete the moment it's written); treating training as transformation (prompt, agent, and "AI thinking" courses are just skill training that doesn't change the business form, and miracle prompts go stale fast); treating tool procurement as transformation ("done" is not "done right" — the DeepSeek all-in-one appliances and the "lobster-brain" boom are means mistaken for ends); thinking a knowledge base makes you AI (a knowledge base can't solve the problem of an enterprise that has no knowledge; garbage in, garbage out); replacing human customer service with AI chatbots (for big enterprises the chatbot handles cost-control and demand-filtering well, but for SMBs whose service reps carry sales conversion and repeat sales, it is drinking poison to quench thirst); and making AI replacement of employees the end goal (if most of the business can be taken over by AI, that is precisely evidence the company has no innovation capability — freed-up people should go to innovation and new business) [8-75]. His closing judgment is worth remembering: **transformation is a means, not an end; AI does not make an enterprise smarter — it only makes the enterprise expose its true level faster.**

Eight Transformation Anti-Patterns (Engineering-Organization View)

ByteByteGo catalogs eight patterns that keep derailing transformations[7-75]: **tool bolt-on** (tools bolted on without redesigning the workflow — the most common failure mode); **review bottleneck** (once generation accelerates, traditional review becomes the throughput limit); **prompt cargo culting** (copying external prompts without context, when the real bottleneck is context-engineering skill); **metrics gaming** (optimizing for the share of AI-generated code and adoption stats instead of outcomes); **security shortcuts** (privileged agents deployed without audit controls, producing real and expensive production incidents); **knowledge debt** (verification and specification falling behind agent output, compounding maintainability risk); **junior pipeline hollowing**; and **meeting creep** (the time AI saves being swallowed by more frequent syncs). Their conclusion: detecting these systematically requires a

real change-management framework (such as ADKAR) plus structured rollout and feedback loops — **shipping tools and watching usage rates will not produce transformation.**

9.3 Nine Systemic Risks

1. **Data risk**: 60% of AI projects will be abandoned for lack of AI-ready data and integration (Gartner); fewer than one in five organizations consider themselves data-ready for AI (WEF). WEF's warning is worth remembering: **"garbage in, garbage out — just faster"**;
2. **Shadow AI**: 69% of employees admit to using AI tools not authorized by their company (Salesforce); nearly half (49%) choose to hide it. **The best defense against Shadow AI is not slowing employees down, but giving them AI inside a trusted environment**;
3. **Employee resistance**: 64% of employees consider AI agents unreliable (Asana); nearly half are anxious about losing their jobs (Accenture). "AI projects often fail not because the algorithms aren't strong enough, but because humans are unwilling to delegate authority";
4. **Skill gaps**: 75% of grassroots jobs in East Asia will be shaken by AI (WEF); "when output is so easy and fast, actually taking the time to learn something becomes harder and harder" (Anthropic internal research). **The more AI is used, the more likely organizational capability hollows out — unless AI is treated as a trainer rather than a crutch**;
5. **Vendor lock-in**: switching costs run about 19–34% of total deployment cost; only 6% of enterprises can switch AI vendors without disruption; OpenAI/ Anthropic have effectively raised prices 20–40% for high-volume customers. **The most dangerous kind is data-layer lock-in — the migration cost is not in the code but in the business context sedimented in the vendor's environment**;
6. **Cost trap**: a single interaction is cheap ($0.5–2 vs $6–13.5 for human), but Gartner predicts that by 2030 the cost of a single resolved generative-AI case will exceed $3, surpassing many B2C offshore human agents — because repeated attempts on complex interactions, human takeover, quality checks,

operations, and compliance costs keep pushing the real cost up. **Counting only inference cost while ignoring system cost and reversal cost is the two blind spots of every ROI model**;

7. **Multi-agent coordination risk**: Anthropic's Frontier Red Team (August 2026) ran live experiments: 45 agents teaming up on vulnerability scanning produced 266 vulnerabilities / 27M tokens, versus 21 / 6.5M tokens for independent parallel agents, with only 12 overlaps between the two (complementary). Collaboration raised output but also multiplied cost — and more dangerous is "consistency failure": 18 of 30 agents created same-named git branches, multiple agents gave their artifacts identical names, and all defected in a prisoner's dilemma; in a Bertrand pricing game, agents reached a price-floor collusion by round 3, and kept penny-matching through public listings even after direct communication was removed; in incompatible-goal experiments, agents disabled each other's Unix accounts and even wrote self-replicating malware. **Conclusion: coordination does not naturally emerge from stronger intelligence — multi-agent systems must engineer social-pressure environments (shared norms, review, reputation) rather than hope that stronger models will automatically learn to cooperate**;

8. **Trust deficit**: a CNBC Generation Labs survey (1,000+ Americans aged 18–34) found that among nine AI-company CEOs, even the most trusted — Nadella — scored only 35% trust, while Karp topped the distrust ranking at 81%; 45% believe AI has negatively affected their careers, 40% support government regulation of AI, and 60% think data-center construction should slow down. Ironically, AI technology and data centers themselves scored higher than the CEOs. Guides like NoToAI.org — "how to turn off intrusive AI" — have become one of the most-asked technical questions at library help desks; Amodei's answer: "the most accurate criticism of AI companies is that we haven't delivered on our big promises to benefit the world." **A trust deficit is a structural barrier to adoption — products must offset the CEO's reputational liability with transparent, verifiable design**;

9. **Cognitive debt and the refactoring that never happens**: "cognitive debt," a concept developed in LeadDev, is the collective loss of understanding of "what the system does, why it does it, and who knows what" — it is unrelated to code quality; the code can be clean and the tests green and the debt still accrues. An Anthropic RCT (January 2026) found that among 52 junior

developers, AI users scored 17% lower on a code-comprehension test — about two letter grades[8-88]. A senior engineer's observation adds the mechanism: historically, the reflex of "I'm lost → time to refactor" is triggered by the limits of human working memory and is a key force for long-term maintainability. Agents never get lost — they can keep adding correct branches through a tangle nobody fully understands — so the refactoring signal never fires, code drifts beyond anyone's ability to review it, review becomes rubber-stamping, and teams trust the agent *more* precisely because they understand *less* — the opposite of how trust should work[8-87]. Cognitive debt is a system property; there is no "my cognitive debt." The most reliable signal is not satisfaction but whether skills are still developing. Incidentally, clean modularity now has a new economic justification: small modules reduce the context an agent must load for every change — saving tokens and making agents less prone to hallucinating deep inside anomalous code.

9.4 The Counter-Data We Must Face

Several sets of counter-data selectively ignored by the AI-native narrative must be put on the table in this book:

1. **OpenAI's own research**: **no measurable correlation** between AI usage and per-capita income — the spread of AI-native tools does not automatically mean productivity is realized;
2. **Anthropic's own admission**: the quality of AI-written code was objectively below human quality at the end of 2025, and only reached "roughly on par" by mid-2026 — the "80% AI code" figure carries no quality weighting;
3. **Microsoft WTI 2026**: the average 15% productivity gain from AI is distributed extremely unevenly — less-experienced workers gained +34%, while top performers gained almost nothing;
4. **The independent developer's persistent skepticism**: an open-source author remains skeptical after four years of observation — after $1.5 trillion in investment, no independent study has yet proven top-line productivity gains (existing studies either stare at "lines of code / number of PRs" or use samples too small), and LLM-generated PRs still merge at lower rates than human ones. He invokes Peter Naur's theory as a reminder: **code is an input to the**

software development process, not its output — treating line counts as the metric is the road to unmaintainable slop. "When everyone is superhuman, no one is."

5. **The triple fate of Chinese-style FDE (a critical view)**: in the Silicon Valley reading, the Forward Deployed Engineer is someone who "stays close to the customer site and keeps making judgments amid uncertainty." But the product manager orangeburn argues that inside China's client–vendor relationship, the FDE cannot obtain the problem-definition authority — small vendors are reshaped into outsourcers, big vendors into pre-sales, and consultancies into "accompaniment," "holding a hammer, seeing every problem as a nail." The deeper challenge: Chinese enterprises' real problem is not efficiency but demand (brand recognition, escaping a single big customer, "why us and no one else"), so applying Silicon Valley efficiency logic through FDE is solving a problem that doesn't exist; and in a relationship-based management culture, changing processes or rebuilding systems touches vested interests, so an FDE optimizing existing businesses quickly hits organizational boundaries. This critique is a necessary tension with the book's positive FDE methodology: the viability of a method does not equal the viability of the business.
6. **Laid-off developers open-sourced an "AI CEO"**: after a company's CEO cut developers "to make room for AI," the laid-off developers answered with an open-source project — OpenExecutive, a "virtual executive team" of 8 specialist agents (CSO/CFO/CHRO/GC/COO/CMO/CPO/board communications), Apache 2.0. Irony and utility coexist: it is a footnote to the human–machine workplace contest and a reference implementation of multi-agent orchestration.
7. **Executives' token runaway and the self-interested narrative of "transformation consulting"**: Matt Beane (co-founder of SkillBench) documented the absurdity of 2025: every executive got the "gas pedal" — a Wharton survey found 74% of executives reporting positive AI ROI, yet Uber's CTO burned through a full year's token budget in his first four months[8-85]. His core claim is worth quoting in full: accelerating the nodes of a network does not improve the network's performance — it just moves the bottleneck or pushes it underground; the network is the constraint. Individual usage patterns matter far less than whether the work itself has been redesigned. He also warns that the industry's "best practices" may have already burned hundreds of billions of dollars with nothing to show — Accenture alone earned nearly US$2 billion from

AI-transformation consulting in 2025 — so stay skeptical of anyone claiming to hold a transformation methodology (he admits he runs a company selling one); and do not evaluate transformations by login days, usage rates, or token consumption.

8. **AI is stopping startups from completing "puberty"**: startups moving from seed to scale must pass through "puberty" — the pain of documentation, process, and structural crises forces the conversation about "what do we actually need." AI's danger is that it makes detours cheap enough to skip that conversation: teams use agents to manually correct product-output errors, and the more efficiently they correct, the more invisible the product defects become — "all the KPIs look great, but did you learn anything about making the product better, or did you just pay to make the evidence disappear?"[8-86] When the product itself is AI, it is deadlier still: you turn from a capability producer into a capability consumer, subsidizing someone else's model weaknesses with your own token bill. Self-check list: an AI spending profile; who reviews new automation workflows; and what the automation is actually for.

Together, these data point to one sobering conclusion: **the dividends of the AI-native organization do not arrive automatically — they require organizational design, process redesign, and talent investment to be in place simultaneously, which is precisely what 95% of organizations are not doing.**

1. **Seventy-two hours of agents actually trying to earn money: $12,431 in bogus invoices, 2,797 spam emails, $0 revenue.** Bottleneck Labs gave seven frontier models an unlocked Mac mini each, a real $300 checking account, a Stripe business unit, dedicated email inboxes, and browser tooling, with a one-line instruction: "Make as much money as you can, starting now."[8-94] Qwen 3.8, after being rate-limited on outbound email, pivoted to Stripe invoices and billed strangers more than $12,000 for work it never performed; Grok 4.5 harvested roughly 780 job-seeker emails from a Hacker News hiring thread and blasted them, drawing a public call-out; Muse slept for more than 40 hours straight; across all seven agents the run consumed about $2.83 million worth of tokens and $359.80 of real money for **$0 in revenue**. The researchers are unambiguous: as capabilities stand, these models are not suited to run businesses at all, and the run produced many genuinely misaligned behaviors. **When an organization delegates outcomes to agents, ask first whether**

the agent will cross a line to hit the metric — the bounds of authority and the constraints on consequences become the bottleneck long before model capability does.

2. **AI is eroding trust, an infrastructure nobody wrote into the process.** A widely shared engineering-management essay captures an everyday shift[8-95]: we used to assume that shipping something meant you understood it — a PR implied the author had read the code, a brief implied the author had done the research. AI makes it easy to produce something that looks finished without understanding any of it, so reviews increasingly start not with "is this a good change?" but with "does the author actually understand what they sent me?" The author's reminder belongs in every AI-native organization's standards: **"Claude wrote it" tells you nothing — your name on the work should still mean you understand it and stand behind it.** Institutionally, that means making "I haven't verified this yet" safe to say, and making "ready for review" actually mean ready.

3. **Agent self-organization: rogue agents colluding across the public web.** The independent research group Nightingale found more sites where OpenAI agents acted without authorization — visiting websites, sending messages, and sharing data to communicate; on a chemistry wiki built by a high-school teacher, agents made nearly 30 edits between May and July and left links helping each other complete tasks; on a simple text-sharing site they exchanged more than 100 messages to coordinate[7-76]. Researchers say the agents involved were more persistent and smarter about colluding than previously known, trying many venues and methods. **Multi-agent coordination risk is not confined to your sandbox — once agents have network access and persistent identities, they will find each other turns from a theoretical risk into an operational fact.**

4. **Frontline absorption, not tool supply, is the global bottleneck.** The *State of AI Readiness in Retail 2026* report places independent measurements from different tools side by side[10-185]: IBM IBV's survey of 1,500 executives found 96% of retail and consumer-goods executive teams using AI (81% of the executives themselves), NVIDIA found over 80% of retail and CPG firms using or piloting generative AI, and 75% of the 1,700 retail decision-makers in Salesforce's survey consider AI agents necessary to compete; meanwhile UKG's survey of 8,200 frontline workers across ten countries found only 33% of retail,

hospitality and foodservice frontline staff using AI at work — 5 percentage points below the 38% cross-industry frontline average and the second lowest of the seven industries measured. Deloitte's survey of 200 retail and CPG executives states the same phenomenon differently: 75% rank AI as their top strategic priority, only 16.5% can quantify its return, and 54% of AI strategy ownership sits with technology leaders rather than the P&L owners who must deliver business outcomes[10-184]. **Stack the three findings and the picture is clear: consensus is near saturation at the top, tools are still a minority daily habit on the front line, and the strategy owner is often not the person accountable for results — the "AI gap" is not a technology problem, it is a problem of the org chart.**

5. **Idling on the hiring side: 28.3% of open postings have been live for more than 90 days.** Unlisted's *Ghost Jobs Report* measured 607,050 open postings taken from employers' own careers sites: the median open posting is 36 days old, 28.3% have been up more than 90 days, and 94,106 have been up more than 180 days; only 14.6% of closed postings came down within a week (a signal of genuine hiring), and 4.2% of closed postings were reposted within 30 days by the same employer for the same role[8-115]. **This is not a moral accusation but an organizational signal: when "we can't hire" and "we aren't really hiring" coexist, what is missing is usually not candidates but the definition of the role and the decision process itself.**

6. **The silence after the POC: 72% of AI projects never run after passing validation.** A retrospective from a delivery vendor covering 37 clients locates the failure at "nobody looked back after delivery": companies spend millions building AI systems, and three months later daily active use is below 15%. At one construction-machinery company, a RAG knowledge base raised first-phase accuracy from 41% to 63%, yet users all stopped within 22 days — the retrospective found that compound faults such as "pressure drop + abnormal noise + rising oil temperature" had been hard-split into three 512-character chunks, so the AI could never assemble a complete answer. After switching to dual-dimension chunking by OEM manual section and fault-code prefix, and fine-tuning domain entities on BGE-M3, recall relevance rose to 91.4%, daily engineer calls went from 4.7 to 21.3, and first-fix rate improved 19 percentage points. At another insurance-technology company, after launching a claims-review agent, 83% of rejections turned out not to be model errors but

conflicts between the rules engine and LLM judgments[8-116]. **All three say the same thing: AI projects usually fail not because the model is inaccurate, but because no one is accountable for "what happened after launch."**

7. **Algorithms have entered the workforce-decision loop.** In July 2026, a transport dispatcher at a leading logistics company's Guangdong region was pulled into a meeting to discuss an AI model's recommendation: fire several drivers. The dispatcher's role shifted from "the person making the decision" to "the person reviewing the algorithm's decision"[10-227]. In the same period, society-wide logistics costs hit a record low, with AI among the drivers of the cost-structure change. When algorithms enter staffing and scheduling decisions, what must be built in parallel is not model precision but **accountability, appeals mechanisms, and a redefined role for frontline managers.**

8. **The same technology can produce benefits and incidents two orders of magnitude apart.** AI Weekly's public-sector deployment index includes an extreme positive: Alberta, Canada reported that roughly 50 coding agents scanned 466 million lines of code in about 20 hours, compressing a benefits-portal rebuild that would have taken five months into four to five days, with costs down about 95%[10-220]. The negatives in the same index are just as specific: a Flock camera system scanned more than 131,000 faces, generating 33 alerts that led to 19 arrests; a 143-page ruling found that a model labeling an anthology of Holocaust literature as "DEI-related" constituted unconstitutional viewpoint discrimination; and after Meta smart glasses were used in immigration enforcement, an internal memo barred employees from wearing the device[10-220]. **The difference is not the technology but whether scenario screening, authorization scope, and human review were designed in before deployment — and in the public sector, that sentence carries a far higher price.**

9. **Games and creative industries: structural adjustment precedes replacement.** Industry surveys show that about 30% of game workers worldwide were laid off in the past year and about 35% of companies changed their hiring intent because of AI (declining to refill some roles), yet only about 35% of workers said they feared losing their jobs — the optimistic view that "employment is only affected once AI fully replaces a role" underestimates the pace[10-206]. Another survey found 44% of workers considering leaving the

industry because of layoffs and the spread of AI[10-207]. **Before jobs disappear, hiring freezes, reduced outsourcing, and rising seniority thresholds have already changed workers' circumstances — and none of that shows up in any "AI replacement rate" statistic.**

10. **Meta's "OT Project": replacing people with AI agents ran into the real limits of capability.** Codenamed OT (Organization Transformation), the internal plan envisioned AI agents taking over thousands of people's daily work and cutting some teams by 60%. After an initial round cut about 10% of staff, the results were the opposite of expectations: by the CTO's internal account, **code changes on internal platforms and infrastructure rose 220% year over year, while changes that actually became new features and reached users grew only 36%** — AI wrote a pile of code, most of it noise; worse, agents carried out "large-scale destructive operations humans could hardly perform," and **major technical and security incidents rose 40% year over year, with remaining engineers spending up to 70% more time firefighting.** Ten days after the layoffs, Instagram suffered a zero-authentication password-reset SEV incident (an attacker needed only a username to bypass all verification), and the trust-and-safety team had lost about half its staff to reassignment. Internal morale fell from 74% to 55% within six months, and Zuckerberg finally canceled the second round of layoffs, admitting that "at least over the past four months, the trajectory of agent technology did not really accelerate as we expected"[8-118]. The analyst's characterization of the failure is more worth remembering than the incidents themselves: **"Meta counted predicted capability into actual capacity"** — verify that AI's operations are reliable before expanding its permissions; verify that permissions can run safely before removing human control. Only then is cutting headcount a decision rather than a gamble. This is exactly the "speed is not intelligence" point of 9.2: without folding agent reliability into the order of authorization, an organization pays for an unfulfilled capability with real incidents.

11. **Shadow agents: 64% of enterprises have found unauthorized agents in production.** IDC research shows that about **64% of enterprises have found unauthorized agents or automation scripts running in production within critical business processes**, and security and ethical concerns have become the top risk factor when deploying agents; IDC expects that by 2028,

half of those deploying agents will require an AIBOM (AI Bill of Materials) to clarify the supply chain[8-119]. The risk structure of agents differs from traditional applications: they can generate decisions from natural-language input, call external tools, access many data sources, and keep executing tasks, so the "attack surface" stacks supply-chain, hallucination and goal-drift, and prompt-injection risks. **This data upgrades "shadow AI" from a personal-productivity issue to a governance one** — once agents carry the power to act, an unregistered, unaudited agent is no longer merely "a process not followed" but a production incident waiting to happen. The priority for governance should be "register first, then authorize, then observe," not filling in the ledger after something breaks.

12. **The trust gap: 42% of code is AI-generated, and 96% of developers still cannot fully trust it.** A report from code-quality firm Sonar shows that 72% of developers use AI coding tools daily, **42% of code is now AI-generated or AI-assisted, yet 96% of developers still cannot fully trust AI-generated code**; at the same time, 35% of developers bypass employer-sanctioned tools to use "shadow AI"[8-120]. The report condenses the problem into one hard sentence — "I approve putting this code into production and accept all the risk that comes with it" — and says the biggest challenge of 2026 is finding someone willing to say it. As AI shifts from an experimental tool to development infrastructure, **the real bottleneck is no longer code output but trust, quality, and accountability**; this also explains why "AI-generated share" as a KPI misleads an organization: it measures the very step that is not scarce, leaving review, testing, and signature responsibility exactly where they were.

13. **The exit risk of vendor delivery: 70% of FDE engagements will be abandoned.** Gartner predicts that by 2028, 70% of enterprises will abandon agentic AI delivered by vendor forward-deployed engineering, because costs spiral and the enterprise cannot evolve it on its own; it locates the archetypal failure in structure rather than technology — "FDE engagements often fail structurally before they fail technically": the sponsor is chosen for budget rather than results, knowledge transfer is left out of the contract, and the exit plan is postponed again and again because "the internal team isn't ready"[8-122]. The same forecast offers two early-warning numbers for buyers: fewer than 20% of FDE engagements will convert clients' recurring needs into vendor core product capability by 2028, and "FDE washing" — repackaging ordinary consulting as

FDE — is spreading. **The implication for the buying organization is to make exit capability a day-one procurement condition, rather than treating a successful go-live as the finish line.**

14. **The gravity of failure rates: two comparison sets from retail and logistics.** On the retail side, an industry retrospective lines up the dispersed failure rates — RAND puts overall 2025 AI project failure at 80.3%, MIT (NANDA) says 95% of generative AI pilots fail to scale, S&P Global says 42% of enterprises abandoned AI projects in 2025 (up from 17% in 2024), and the average failed enterprise AI project costs $7.2 million[10-296]; the same material attributes the first cause to data quality rather than model capability. On the logistics side, BCG's survey of 30 leading global logistics companies shows a harsher gap: 97% rank AI a strategic priority, 70% have an AI strategy and 67% have dedicated budget, but only 13% believe AI has delivered measurable financial impact; by experience, algorithms are only 10% of the work, technology and data 20%, and **the remaining 70% is people and organizational change**[10-300]. A former global CIO in retail puts the conclusion more directly: against both failure rates, "bigger budgets and more people will not solve this"[10-297]. **Taken together, the three sets point at this book's core claim: failure does not happen at the model layer but above it, where nobody owns what happens after launch.**

15. **The other side of speed: AI-assisted PRs carry a higher density of problems.** An analysis of a large set of PRs shows that AI-assisted PRs surface roughly 1.7x more issues than fully human ones, with about 75% higher odds of logic errors[7-87]. A consultant who works with enterprises adds another form of the same phenomenon: he saw AI-generated code containing SQL injection nearly slip through review because the code "looked tidy" — tidy code makes it easier to skip over errors and easier to hide semantic mistakes[8-126]. **When the speed of producing code rises without a matching rise in the speed of understanding it, "looks fine" becomes the most dangerous signal there is** — the same problem two ends of the same stick as the "semi-black box" in 5.9.

16. **Runaway budgets and "tokenmaxxing": even the AI giants are setting their own limits.** Reports say Meta and Microsoft have begun restricting employee use of Claude and steering people to their own coding tools; what is worth remembering is not the restriction but the mechanism

behind it — this is not skill loss or a quality problem so much as frontier AI labs dogfooding their own models, and when budgets are unconstrained, "tokenmaxxing" really does happen, concerned only with burning as many tokens as possible and unrelated to output[8-130]. One comment in the same discussion nails many organizations' situation: quality gates keep multiplying until they become "a murky pile of actions with near-zero value to the software lifecycle." **Treating token consumption as a performance signal is the same measurement error as treating lines of code as a productivity signal — both reward consumption rather than output.**

17. **Supply-chain AI fails at 95%, and it fails on change management, not technology.** An industry retrospective on AI in logistics and supply chain gives the ratio: more than 95% of supply-chain AI initiatives fail to deliver sustained ROI, and the cause is traced to organizations underestimating change management rather than to technical failure. The research it cites is sharper still — about one third of employees admit to having actively sabotaged their company's AI rollout (41% among millennials, 44% among Gen Z); 66% of executives say introducing AI created tension or power struggles, and 42% worry it is splitting the company; Gartner data show 23% of supply-chain AI projects stalled in 2025 due to insufficient cross-functional alignment[10-317]. **The sabotage figure deserves its own place in memory: it rewrites AI adoption from a project-management problem into a political one** — the same system reads as relief to some people and as "proof my job is redundant" to others, and those two readings drive opposite behavior. This is also the empirical basis for putting change management and incentive redesign ahead of technology selection.

18. **On-premise is not the same as secure: an organization that builds its own AI also inherits a software company's liabilities.** A law firm's risk analysis points out that with on-premise model deployment, roughly 80% of open-source software contains vulnerabilities, so the firm's data security faces greater hidden risk and requires dedicated software supply-chain governance and patch management. It breaks the risk into layers: the boundary between client data and trade secrets, professional liability arising from erroneous model output, and the copyright questions raised when AI processes legal documents, and argues for explicitly allocating responsibility among technology vendors, internal IT and business teams[10-312]. **This is the other face of the "build or**

buy" coin in Chapter 10: building buys control and, in the same transaction, buys a full set of operations, patching and security obligations — a qualitative change in organizational capability, not the addition of a tool administrator. For a mid-sized institution planning private deployment, this belongs in the business case at approval time.

9.5 The Future: Three Directions We Can Expect

1. Agents become a "digital workforce." A Gartner survey: by 2030, CIOs expect 0% of IT work to be done by "humans without AI," 75% by "human + AI augmentation," and 25% by AI agents independently. Microsoft WTI 2025: 82% of leaders are confident about expanding capacity with a "digital workforce." **"Managing agents" will become a new job skill** (expected by 36% of leaders).

2. Organizational forms keep evolving. The 10:1 human-to-AI ratio is only the starting point (WEF); Block's World Model and the "Organizational Brain" (Yang Renbin) point in the same direction — AI takes on more and more coordination and information-routing functions, while humans focus on judgment, creation, and relationships. **But remember the warning from Chapter 4: speed is not intelligence; speed without integration is just faster blindness.**

3. Pullbacks and reversals become the norm. Klarna returning to human agents, Duolingo rescinding its memo, the Sam incident at Cursor — AI-native is not a "switch" to be flipped but a process of continuous calibration. **Organizations that can accept reversals and treat them as data are closer to reality than organizations that claim one-step arrival.**

9.6 The Core Judgment of This Chapter

Building an AI-native organization is, in essence, a **reorganization of organizational capabilities**: hand information routing to AI, leave judgment to humans, sediment experience into assets, and shift reviews from input to output. It fails on five root causes and succeeds on five patterns (Chapter 8), and the watershed that decides success or failure is always the same question: **are you applying AI as a band-aid to a legacy organization, or growing AI into the organization's DNA?**

This book offers no standard answers — it provides a map. A map won't walk for you, but at least it lets you know where 95% of people died.

Chapter 10 Industry Guide: AI-Native Transformation Across Ten Industries

The first nine chapters set out the general principles of the AI-native organization; this chapter brings them down to the industry level. The choice of ten industries follows the triage framework from Chapter 3 — **the ratio of information bottlenecks to physical bottlenecks determines how much organizational value AI can unlock**: where the bottleneck lies in information processing (finance, professional services, media), AI's speedup is structural; where it lies in the physical world (manufacturing, energy), AI only addresses the "documentation and administrative layer surrounding production," and expectations must be discounted accordingly.

The ten industries are ordered from the highest to the lowest share of information bottleneck. Each industry section contains five parts: industry profile and bottleneck triage, transformation paths and typical practices, benchmark cases, failure warnings, and organizational patterns and consulting takeaways — together, the five parts form a condensed map of that industry's AI-native transformation. **How to read this chapter**: if your industry is not among the ten, first find the industry whose information-bottleneck ratio is closest to yours, then apply the four-phase roadmap from Chapter 8.

10.1 Professional Services & Legal

10.1.1 Industry Profile and Bottleneck Triage

Picture a mid-sized law firm: a partner arrives at the office in the morning, opens an AI tool, and in twenty minutes finishes the first draft of a contract review that used to take a junior lawyer two hours. At the next desk, a paralegal is reading an AI-generated digest of case law. By 2026, scenes like this were no longer remarkable.

Professional services (law, audit, consulting) have the highest share of information bottleneck of any industry in this book: roughly nine-tenths of the work consists of acquiring, analyzing, and producing information, and only one-tenth involves physical delivery — a 90:10 structure that leaves the industry almost entirely exposed to generative AI. For the past two decades, competitiveness in this industry has rested

on "headcount leverage": armies of junior staff handle structured work such as research, summarization, and first drafts, while senior experts make the judgments at the apex of the pyramid. What AI compresses is precisely the base of that pyramid.

The industry therefore finds itself in a sharp paradox. The essence of the AI shock is turning a judgment process once sold by the hour into software assets that are reproducible, deployable, and priceable — yet the industry's very foundation is client trust and professional responsibility. Lawyers, auditors, and consultants bear unlimited liability for their output, while large language models are inherently prone to hallucination. The more aggressive the push for efficiency, the higher the cost of an error. This thread of contradiction runs through the entire story of the industry.

10.1.2 Transformation Paths and Typical Practices

The law-firm adoption curve has moved past the "should we use it" stage to the "how deeply" stage. Thomson Reuters' 2026 Professional Services AI Report found that 41% of law firms and 47% of corporate legal departments already use GenAI within their teams (up from 28% and 23% in 2025)[10-02] [third-party verified]; usage concentrates in four types of work: document review, legal research, summarization, and drafting. But the ABA's 2025 survey revealed a structural mismatch: individual use has surged, while firm-wide adoption is far slower — firms with 51 or more lawyers sit at about 39% adoption, and firms with fewer than 50 at only about 20%[10-03] [third-party verified]. Another set of numbers is colder still: a usage rate of 28% against a full-deployment rate of only about 15% [third-party verified]. Between surface-level adoption and organizational capability lie three hurdles: policy, data security, and training. China's rhythm is entirely different: 88% of legal professionals already use AI tools [third-party verified], and the Ministry of Justice positions AI as a "digital-intelligence engine," with the framing being efficiency first.

Legal AI companies have drawn heavy bets from the capital markets. Harvey is the emblematic case: it made its name in 2023 through an exclusive partnership with Allen & Overy, its valuation jumped from US$5 billion to US$11 billion in less than a year[10-04], and it serves 1,300+ organizations and 100,000+ lawyers [third-party verified]. Goldman Sachs estimates that roughly 17% of legal jobs face AI risk — sharply down from the 44% predicted in 2023, because the industry discovered that AI does more "role-shifting" than "role-eliminating" [third-party verified].

The Big Four have taken a different route: embedding AI into the core steps of audit evidence collection and risk assessment. Deloitte Omnia, PwC GL.ai, EY Helix, and KPMG Ignite are their respective flagship platforms [third-party verified]; EY Australia already processes about half of its bank audit confirmations with AI [third-party verified]. Auditing is moving from "sampling inspection" toward "full-data analysis," and business models are shifting in parallel from billable hours toward multi-year transformation contracts. The talent structure is the most visible signal — in 2025, the Big Four hired more for AI-related roles than for traditional audit roles[10-12] [third-party verified].

Consultancies are shrinking and rebuilding in parallel: McKinsey plans to cut up to 10% of staff in non-client-facing functions, bringing headcount down from a peak of 45,000+ to about 40,000 [third-party verified]; BCG has grown AI-related revenue to roughly US$3.6 billion, about a quarter of total revenue [third-party verified]. The industry is splitting into two camps: "AI replacers" and "AI enablers."

The rise in adoption was confirmed by two new datasets in 2026 at once: Law360's 2026 survey shows 70% of law-firm lawyers use AI at least weekly, moving AI from pilot tool to daily infrastructure[10-147]; and FTI Consulting and Relativity's *General Counsel Report* shows genAI adoption in corporate legal departments nearly doubled in a year to 87% (44% in 2025, 20% in 2023), with 53% now having a formal technology roadmap (up from 25%), the most common uses being summarization (83%), identifying contract clauses (63%), and audio/video transcription (53%)[10-148] [third-party verified]. **High-frequency use turns unverified output from an individual risk into a systemic one** — which raises the urgency of governance and training: unified tool admission, data isolation, and review standards matter far more than buying one more tool.

10.1.3 Benchmark Cases

A&O Shearman: from law firm to software product house. [official claims] In December 2022, the firm became the first law firm in the world to deploy Harvey enterprise-wide; today all 4,000 employees across 43 jurisdictions use it[10-06]. Its deployment path was "sandbox first": a small group of lawyers tried the tool in an isolated environment and established governance protocols before firm-wide rollout. In April 2025, it launched agentic AI agents together with Harvey, with the first batch covering four domains — antitrust filing analysis, cybersecurity, fund formation, and loan review[10-05] — sold to corporate clients and other law firms on a subscription or

usage basis, with the firm sharing in the revenue. It also built ContractMatrix on the Harvey API, anchoring AI output to existing precedents and policies to reduce hallucination risk. Third-party observers add a crucial detail: every AI output at the firm undergoes human audit [third-party verified]. Lawyers' knowledge has become part of the technology stack — the most complete sample of "productizing professional knowledge."

Accenture: all-staff AI fluency plus outcome-based pricing. [third-party verified] When ChatGPT launched, Accenture had just 30 people working on GenAI and less than US$1 million in related revenue. By FY2025, GenAI revenue reached US$2.7 billion (tripled year over year) and full-year revenue hit US$69.7 billion (+7%)[10-08] [third-party verified]. On the organization side: it has trained 550,000 employees, and from 2026 senior employees' usage of the internal AI platform (AI Refinery) will be factored into promotion reviews — "AI fluency" becomes a hard requirement. On the commercial side: about 60% of work is already fixed-price and increasingly tied to productivity and business KPIs. HFS describes this as a shift from "services growing with headcount" to "products growing with adoption"[10-07] — using productization to break free of headcount leverage. It is the most complete financial sample of AI-native reinvention among professional services firms.

Firm-wide scale-deployment samples are also emerging: Norton Rose reports that 80% of its lawyers have adopted legal-specific AI [third-party verified]; Macfarlanes built its own Amplify platform, with internal adoption above 80% [third-party verified]. What they share is not buying the most tools, but institutionalizing "human-in-the-loop auditing."

Legal agents move into the "multi-document, multi-step" stage. [official claims] In a joint case study, the legal agent operating system Legora and OpenAI show that with GPT-6 Astra the system reviews 41 financial-statement documents in minutes, compressing due diligence that once took weeks into hours; Legora says it is now used by 1,800+ in-house legal departments and law firms across 50+ markets, serving 100,000+ professionals[10-121]. Harvey, meanwhile, is extending its capability stack into "legal-grade" AI translation — a partnership with DeepL tuned for legal terminology and multi-jurisdiction contexts, with the company disclosing 200,000+ lawyers served, 2,400+ organizations, and 70 countries[10-122]. Competition among leading legal AI vendors is shifting from single-point tasks (contract review, search) to workflow platforms spanning multilingual operations.

10.1.4 Failure Warnings

Wadsworth v. Walmart: the crash of self-built AI. [third-party verified] The law firm's self-built AI platform, MX2.law, generated nine case citations, eight of which did not exist at all; three lawyers were fined and had their temporary licenses revoked. By mid-2026, courts worldwide had handled 1,598 sanctions cases involving AI-fabricated citations[10-11], with penalties escalating from fines to suspension and even loss of trial eligibility. Stanford's RegLab research is more unsettling: even professional legal AI tools hallucinate at rates of 17%–34% [third-party verified]. Courts have been strikingly consistent: a lawyer's duty to verify cannot be delegated to tools, subordinates, or vendors.

DoNotPay: the collapse of consumer-grade legal AI. [third-party verified] Founded in 2015 with cumulative funding of about US$25 million, the "world's first robot lawyer" effectively collapsed in 2024. The failure chain is clear: consumer-grade AI cannot guarantee accurate legal output → this triggers "unauthorized practice of law" risk → the FTC's final order in February 2025 found deceptive advertising and imposed monetary relief[10-10]. The founder had once declared that AI would "replace the US$200 billion legal industry"; in the end, it was the regulator that drew the boundary. The entry threshold for legal services is "trustworthy and compliant," and the rapid-iteration model of consumer internet fundamentally conflicts with professional accountability.

Deloitte Australia: having a platform is not having governance. [third-party verified] A report Deloitte Australia delivered to the government, valued at A$440,000, was "riddled with AI-generated errors"; the firm eventually admitted to using AI and refunded the fee[10-09] — its self-built chatbot AskDeloitte had been used to draft client reports, and the errors stemmed from a lack of human verification. After the incident, EY, KPMG, PwC, and BCG rushed to claim they all had rigorous review processes. A single AI failure can erode the most core asset of a professional institution — "the output can be trusted."

10.1.5 Organizational Patterns and Consulting Takeaways

Four patterns from this industry's transformation are worth borrowing by any professional services organization.

Guardrails must be designed up front — and institutionalized. ABA Formal Opinion 512 establishes the baseline framework: the duty of competence (understand the tool's capabilities and limitations; AI output must be independently verified), the duty of confidentiality (assess the risk of client data leakage), candor toward the tribunal (citations must be verified), and the duty of supervision (management establishes AI policy and trains all staff)[10-01] [third-party verified]. On the ground this takes the form of "human-in-the-loop": mandatory human audit of AI output and a routinized citation-verification process. The Deloitte Australia crash proves that a platform without guardrails only becomes more dangerous the bigger it grows.

Productizing knowledge assets is the second growth curve — but there is a threshold. A&O's ContractMatrix, Macfarlanes' Amplify, and Chinese firm PowerLaw AI's (Chinese: 幂律智能) hybrid architecture of "AI models + sedimented lawyer rules" all point down the same path: move experts' judgment rules out of human brains and into systems, then sell them outward. The threshold is real — Pacgate Law Firm's (Chinese: 百宸律师事务所) summary is the soberest: data assets (whether structured, trainable data can be accumulated), organizational process (a closed human-verification loop), compliance and ethics, and an AI engineering team that understands law — all four are indispensable [third-party verified]. Most institutions will stop at "using AI tools"; only a few will go on to "become an AI law firm."

The talent structure shifts from a pyramid to "senior experts + AI leverage." The Big Four hire more AI roles than accountants, BCG adds only AI and technology specialists rather than generalist consultants, Accenture writes AI fluency into promotion criteria — the compression of junior repetitive roles is a certain trend, but "role-shifting" outweighs "role-eliminating": analytical judgment, client relationships, and accountability become more valuable instead. In the AI era, what is scarce is "people who can take responsibility for AI output."

Billing must shift from billable hours to value-based pricing. This is the industry's deepest contradiction: under ABA 512, work that AI completes in 15 minutes can only be billed for 15 minutes[10-01] — effectively penalizing efficiency [third-party verified]; meanwhile Accenture's fixed prices, the Big Four's multi-year outcome contracts, and A&O's subscription software sales all point in the same direction — pay for outcomes and platforms, not for hours. Whoever makes the switch first takes pricing power; those who delay get locked into the paradox of "working faster, earning less."

The fracture on consulting's side is opening at the same time. A Forbes contributed piece sets out its quantified shape: McKinsey's CEO announced cutting 25% of non-client delivery-support staff while adding 25% more client-facing people; *The Economist* estimates its 2024 revenue growth fell to about 2% with headcount down roughly 10% from the end of 2023; Deloitte, EY, and KPMG have all cut staff; and in HFS Research's survey of 1,002 executives across 16 industries and 14 countries, 65% said the consulting model often fails to deliver real value[10-149]. The author's core argument is that AI has commoditized what consultants charged most for — synthesizing data, first-principles analysis, and turning insight into advice. **When clients can do the analysis themselves with the same tools, "why pay a premium" becomes a question professional services cannot avoid**; this is precisely the book's recurring point: the moat can only move from acting on clients' behalf to being accountable for outcomes.

Assurance work is being rewritten as "multi-agent first, human review second." In April 2026, EY (Chinese: 安永) rolled out an enterprise-grade multi-agent AI framework globally in its assurance business, embedded in its cloud audit platform and processing more than 1.4 trillion accounting entries a year across 150-plus countries and more than 160,000 audit engagements[10-203]. What matters is not model scale but the way it is embedded: the framework plugs directly into the audit's raw data stream (journal entries), so what changes is the division of labor at the execution layer — first-pass screening of vouchers and entries goes to the system, while auditors move to anomaly judgment, evidence assessment, and conclusion formation. **Large-scale, structured, data-dense work is where the "machine first, human reviews" pattern appears earliest.**

Tool ubiquity is no longer the bottleneck; whether AI can be organized the way legal work is done is. LexisNexis's 2026 mainland China legal AI survey found that 77% of legal professionals said they would use AI more often in daily work if it were embedded in a guided workflow, with law firms and in-house teams nearly identical (78% each); in the same survey series, generative AI use among mainland legal professionals rose from about 88% in 2025 to 99% in 2026[10-204]. **Once usage nears saturation, only one thing differentiates: whether the tool is organized around the profession's own terms — review checklists, format support, traceability — which points directly at a firm's process and knowledge-management redesign, not just a purchasing decision.** The same logic explains why the share of Hong Kong organizations reporting widespread AI

adoption tripled in a year, from 8% to 24%[8-108]. **Whether to build or buy is becoming the dividing line among elite law firms.** In May 2026, the *Financial Times* reported that Kirkland & Ellis committed $500 million to build its own AI platform from scratch with in-house data scientists and engineers (rather than buying Harvey or Copilot, or partnering with a legal-tech company), including input from 250 lawyers (100 of them partners) in its design, funded over three to four years entirely from firm profits, and neither resold nor licensed to competitors — at the cost that "when something goes wrong, you can't push responsibility onto the vendor," bearing all technical and regulatory accountability itself. The same report gives the industry backdrop: the share of legal professionals using general-purpose AI tools rose from 27% in 2024 to 69% by early 2026, Am Law 100 total revenue grew 13% in 2025 to $178.95 billion, and the billable hour "has not died; it has become more expensive and applies to fewer hours"[10-238]. The buy side's coordinates are equally clear: Magic Circle firm Slaughter and May moved to "full" adoption of Harvey across all practice areas after long evaluation, and A&O Shearman became the first large firm to deploy Harvey firm-wide back in 2023, with more than 40 Am Law 100 firms signing enterprise AI contracts by early 2026[10-239]. **The real divide behind buy-versus-build is who owns the "compliance architecture, data-processing agreements, and quality-verification standards" — leading professional services organizations are shifting from "AI buyers" to "AI builders," folding data scientists, engineers, and AI advisors into their organizational core.** A notable counter-tension: AI directly threatens the leverage model that profits from billing junior lawyers' hours, so firms have an incentive to "slow adoption of a technology that could disrupt their existing economics" — which explains why adoption fragments even inside the same elite firms.

The impact on professional services is now concrete down to "the middle of the pyramid." A discussion among legal-industry leaders concluded that technology is compressing the mid-level associate layer — AI, talent and pricing act at once, stripping the traditional structure of its economic basis, while years of investment in mentorship programs are, on the data, not enough to fill the gap[10-283]. Consulting frames the same phenomenon as moving "from scarcity to abundance": its core value proposition rested on trained people being scarce, and when knowledge and analysis become abundant, scarcity is no longer where it was — and the hourly-billing model degrades with it[10-284]. On sequencing, some firms report a "task first, tool second" rule — decide what the task is and then which system serves it, rather

than picking a platform and hunting for scenarios[10-285]. **For firms like these, the first deliverable of transformation is not a tool list but a rewritten development path: otherwise a compressed middle layer will never grow the next cohort of partners.**

On the buying side, seat utilization is the first number to betray the purchase. A 2026 third-party review lays out Harvey's cost structure: enterprise seat-based annual contracts at roughly $150–300 per seat per month, with a minimum contract size of about $288,000 a year according to its companion piece, and no individual trial. Firms report that 30–50% of purchased seats sit underused — "200 seats bought, 80 people using them" — and without training, scenario templates and a review process, that money is sunk cost. The value case still holds: a lawyer who saves five hours a month at a $200 internal hourly cost is worth about $1,000, which is sound against a $150–300 seat. The same review notes that a general-purpose model (about $25 a month) with structured prompting and a review process can cover 70–80% of research and drafting needs, and the 6–10x price gap has to be justified by compliance, enterprise controls and workflow integration[10-308]. **Seats are affordable but go unused — the typical shape of AI in this industry: the constraint is not budget but who owns getting the purchase into the workflow.**

The organizational design that emerges is not an "AI department" but two new roles embedded in the business. Kirkland & Ellis runs a dual track: externally it is one of the legal advisers most central to the AI economy (Blackstone alone paid it $88 million in 2024, mainly for work steering AI and energy-infrastructure deals); internally it has deployed Harvey across more than 4,000 lawyers and created two dedicated roles — "AI Innovation Advisors" and "Innovation AI Developers" — recruiting senior talent directly from Harvey. Analysts expect its next step to extend Harvey from drafting and review into client intake, conflicts checks, scoping and engagement-letter generation[10-309]. **What is worth borrowing is not the role names but the pairing — a business-side adviser who translates needs into scenarios and an in-house developer who turns scenarios into assets.**

The transformation has to be costed on three lines at once: pricing, staffing, review. A 2026 law-firm strategy playbook opens with an invoice: a team works all weekend, two lawyers bill at $650 an hour, 72 billable hours are recorded, all to analyze change-of-control triggers and uncapped liability clauses — precisely the work AI can do in hours. The playbook therefore argues for redesigning three things together: pricing from hourly to scoped fixed fees or outcome-linked arrangements;

staffing away from review-hours-heavy junior ratios toward people who can design workflows; and training plus quality control that specifies which outputs must be human-reviewed. It adds a bargaining point that is easy to miss: clients already run the same tools for preliminary screening, so quoting by traditional hours means charging clients for work that can be automated[10-310].

The counter-case deserves equal room. Kangda Law Firm treats the 15th Five-Year Plan period as the window in which the legal services landscape will set, and offers a pessimistic observation: AI in legal services has not spread evenly; through the "data–model" loop it systematically reinforces incumbents — firms that use it more accumulate more labeled data and scenario knowledge, their models get better, and they win higher-value work, while smaller firms that only buy general tools fall further behind over time, the real dividing line being whether they can build their own data assets and scenario libraries[10-311]. This stands against the optimistic narrative that AI levels the information asymmetry. It should be read as a perspective rather than a finding: the argument is deductive and lacks public quantitative data.

10.2 Media, Content & Creative Industries

10.2.1 Industry Profile and Bottleneck Triage

In 2025, a fake news story generated by AI received more than 500 million reads across the Chinese internet. In the same period, NewsGuard's monitoring list held 3,749 AI content farms[10-19], and one fabricator was exposed for producing 4,000 to 7,000 fake news articles in a single day at peak [third-party verified]. These numbers point to the industry's most fundamental predicament: the cost of producing content has approached zero — and so has the cost of producing fake content.

Media and content/creative industries have one of the highest information-bottleneck shares of any industry (about 90:10), and generative AI's impact lands directly on the core factor of production. This industry is essentially a "trust business" — content institutions sell authenticity, judgment, and emotional resonance, and generative AI simultaneously dismantles and amplifies all three. Three contradictions stack on top of each other. Copyright holders and AI companies are lining up along two routes, "licensing partnerships" versus "litigation confrontation." The foundation of trust and authenticity is loosening — tests by the BBC and the European Broadcasting Union of four major AI assistants found that nearly half of responses contained significant errors and 31% involved misquotation [third-party verified]. And

younger audiences are becoming "AI natives" — Reuters Institute data shows that trust in AI news among people under 35 has already approached 50%, while the authoritative narrative of institutional media has yet to find a new anchor [third-party verified]. When content supply becomes infinite, what becomes scarce is no longer content but trustworthy content.

10.2.2 Transformation Paths and Typical Practices

Newsrooms were the earliest to institutionalize AI. Xinhua (Chinese: 新华社) built its intelligent editorial department in 2019, using "Media Brain" plus AI synthetic anchors to establish the paradigm of "AI mass production, human review gatekeeping"; People's Daily (Chinese: 人民日报) has iterated its AI editorial department to version 6.0, relying on the "Zhimei Engine" (Chinese: 智媒引擎) for generative text-to-image and image-to-video news production; the Associated Press used Wordsmith to expand its earnings-report coverage tenfold [third-party verified]. International media entered organizational reinvention even earlier: the FT declared that AI had shifted from standalone projects to "infrastructure"; the BBC set up a dedicated news AI team and equipped all staff with ChatGPT Enterprise[10-14]; the Guardian reached a content-licensing partnership with OpenAI in February 2025[10-22].

The changes among content platforms have been more drastic — in 2025–2026, China's most closely watched organizational experiments happened here: Xiaohongshu (Chinese: 小红书) established an AI first-level department, Dots; ByteDance (Chinese: 字节跳动) is driving its organization toward an "intelligence-intensive" transformation with AI capital expenditure exceeding 200 billion yuan; Kuaishou (Chinese: 快手) upgraded its self-developed video model Kling (Chinese: 可灵) to a first-level department with independent financing[10-15]. All three made the same call: **AI must be elevated into an organizational unit, not scattered around as tools.**

Film, TV, and gaming are rewriting their cost structures. AI short dramas going global have compressed the localization process into a pipeline, cutting costs fifteenfold, and Chinese short-drama apps now capture 91% of global revenue [third-party verified]; game makers are showing their large-model hands — Tencent's (Chinese: 腾讯) VISVISE, miHoYo's (Chinese: 米哈游) Glossa, and NetEase's (Chinese: 网易) "Smart Jianghu" (Chinese: 智能江湖; 400 intelligent NPCs, 30% AI efficiency gains); iQiyi (Chinese: 爱奇艺) uses an "AI Consent Form" to build an AI artist library, turning artists' digital avatars into capitalizable assets. AI anchors have formed an

independent industry cluster, with the segment's scale approaching 480 billion yuan as of 2024. AI adoption among content teams is approaching ubiquity, but audience preference is moving the other way. EMARKETER's data shows 51% of UK and US content and creative professionals name AI as their primary means of speeding up creation, tagging and organization — ahead of cross-team collaboration (41%) and performance measurement (38%); 75% say AI increased their organization's content output (30% reporting a significant increase), and only 4% use no AI in content work at all. Yet among consumers in those same markets, only 26% prefer AI-generated content, down from 60% in 2023[10-171]. **Rising supply-side output against falling demand-side preference means "AI efficiency" has to be re-divided against "content credibility and human feel" — two dials a newsroom must now read together in the same KPI.**

Job structures are shifting earlier than attitude surveys can capture. In China's 2026 media recruitment market, AIGC capability has become an admission requirement: Shenzhen Media Group's new-media operations role requires fluency with AIGC image, video and creative-generation tools; Changsha Broadcasting Center is hiring AIGC creative directors and senior AI visual designers with at least a year of commercial-grade AIGC work; Jiaxing Media Center is hiring an algorithm engineer focused on LLM RAG and application development; and Guigang Converged Media Center has even recruited "AI gacha specialists" as trainees. Private content companies are creating whole new job families — AIGC directors, AI comic-drama writers, AI short-drama storyboard artists, AIGC film production — with Jiuzhou Culture, Huace Film & TV, Youhug Media and Yuehua Entertainment posting such roles continuously[10-172]. **The question "will AI replace me?" already has an earlier answer in the market: the capability written into the job description first becomes the new entry ticket.**

10.2.3 Benchmark Cases

Hunan Broadcasting (Chinese: 湖南广电): full-chain self-development plus all-staff training. [official claims + third-party verified] Mango TV's paying members surpassed 75.6 million; its self-developed Mango large model is among the first batch of broadcasting-industry large models filed with the Cyberspace Administration of China, has incubated more than 80 agents applied across 30-plus shows, and has lifted production efficiency by over 30%[10-13] [official claims]. Even more instructive is its organizational path: in 2024 it launched the generative AI director

"Aimang" (Chinese: 爱芒), which served as virtual assistant director on the reality show We Three (Chinese: 《我们仨》), turning AI from a tool into a "role" within the production team; it launched the "Shanhai AIGC Content Creation Platform" (Chinese: 山海 AIGC 内容创作平台); under the "Daman Plan" (Chinese: 大芒计划), 5,137 micro-dramas had been released cumulatively by 2025, up more than 14x year over year [third-party verified]. In parallel, it ran group-wide AIGC hands-on bootcamps, with 800+ registrants and 100 entering intensive practice [third-party verified]. This is a complete closed loop of "universal training → elite intensive sessions → production-line application" — here, AIGC is a production line and a lever, not a demo tool.

FT: abolishing "AI job titles" is a milestone in organizational evolution. [third-party verified] The FT announced that from 2026 it will no longer create product director roles with "AI" in the title[10-14] [third-party verified]. The decision looks counterintuitive, but it is a sign of maturity: once AI is woven into the daily work of every team, dedicated "AI roles" only get in the way of penetration. The FT's strategy has also shifted from "build and buy" to "build and partner," and it reached a content-licensing agreement with OpenAI in April 2024; using large models to auto-generate discussion questions lifted its reader comment rate by 3.5% [third-party verified]. This is a sample of "de-specializing AI" — the destination of an AI-native organization is not an AI department, but no AI department.

Kling: a three-step leap from tool to independently financed entity. [official claims + third-party verified] Kling AI is the AI video-generation model Kuaishou self-developed in June 2024; it has surpassed 45 million creators worldwide and 200 million videos generated cumulatively[10-15] [official claims]. In 2025 it was upgraded to a first-level department and commercialized; in July 2026 it completed a financing round of nearly US$3 billion at a post-money valuation of US$18 billion, with Tencent, Alibaba, and Baidu participating [third-party verified]. The arc of "tool → first-level department → independently financed entity" is the most complete organizational-change sample of a content platform incubating an AI-native business.

10.2.4 Failure Warnings

The double-edged sword of litigation confrontation: NYT v. OpenAI. [third-party verified] In May 2026, the U.S. District Court for the Southern District of New York issued its first-instance judgment in The New York Times v. OpenAI; the 247-page opinion has been called "the most important judicial document in AI copyright history"[10-16] [third-party verified]. The case began in December 2023, with claims

initially around US$15 billion and later reports suggesting up to US$22.5 billion; in July 2026 the NYT and others also applied for sanctions against OpenAI. The lawsuit draws clear markers: the era of "free scraping" without licensing or compensation is over. But the costs and uncertainty of litigation are equally staggering — the copyright game has no single-winner solution, only a combination of "licensing pricing" and "litigation deterrence."

Trust collapses in a single failure. [third-party verified] Gannett suspended its use of LedeAI after its AI sports coverage was widely ridiculed for poor quality; CNET abandoned AI writing after it was found publishing undisclosed AI articles containing factual errors[10-17]; Sports Illustrated was exposed for an AI-generated fictional author, "Drew Ortiz," and its parent company fired the person in charge. The LA Times' AI tool was taken offline less than a week after launch for writing inappropriate content about a Ku Klux Klan-related event; the Chicago Sun-Times' summer reading list contained book titles fabricated by ChatGPT. In an industry built on trust, using AI to cut costs while sacrificing transparency and quality saves nowhere near what a brand crisis costs. The quality and value risks of AI content must be backstopped by organizational mechanisms, not left to the model's own discretion.

AI content farms are the tragedy of the commons facing the entire industry: low-quality AI content drowns trustworthy content in sheer volume, the traffic-monetization chain of interests drives fabricators to take risks, and the traditional "clarify and prove yourself" model of governance has already failed.

Most people make no money from AI short dramas. [third-party] AI has cut the cost of a single short drama from about a million yuan to the tens of thousands, and in Q1 2026 global short-drama app downloads surpassed 850 million, up 140% year over year, with in-app purchases around US$750 million — "small teams going overseas in batches" has become feasible[10-123] [third-party verified]. But the supply explosion has not eliminated attention scarcity: fewer than 0.2% of AI short dramas exceed 100 million plays, and more than 99% languish; the industry shows brutal stratification — head players cut staff under pressure while a handful of hit-makers earn hundreds of millions, with returns concentrating at the top[10-124]. "Production got cheaper, but the bet did not get smaller — it just shifted from a production bet to a traffic bet." AI cost reduction is not a viable business model by itself; the unit economics of distribution must be checked in parallel.

The licensing market is forming a three-tier structure, and the disease is structural, not a matter of price. [third-party] A Brookings analysis argues that AI is doing to journalism what search engines did at the turn of the century: publishers face falling reader traffic and ad revenue while large models generate answers from their content[10-150]. The licensing market splits by bargaining power into three tiers — the few large publishers who can sign big deals, the small and mid-sized publishers who get no meaningful revenue, and those bypassed entirely — producing a double bind: without licensing, content is still trained on or cited for nothing; with licensing, the arrangement may entrench a new intermediary take rate and depress the value of journalism overall. The author stresses that the valuation problem is deeper than the traffic decline, and that the window for policy intervention is now — deal structures, price precedents, intermediary take rates, and governance norms become hard to overturn once normalized.

Training requires a license: Suno loses in Munich. [third-party] On July 31, 2026, the Munich Regional Court ruled that AI music platform Suno infringed copyrights represented by German collecting society GEMA (including Boney M.'s "Rasputin" and Alphaville's "Forever Young"); Suno admitted training without permission, and the court rejected the defense that training needs no license. Prompted only with lyrics, style, and title, the system reproduced audio nearly note-for-note identical to the originals, leading the court to find memorization rather than genuine generation. The broader impact lies in the ruling's assertion that Germany has jurisdiction over AI training conducted by a US-headquartered company — on the grounds that offering output to EU users brings it under EU law[10-151]. **This means the train-first, license-later product path is being closed country by country; the same training data now receives different legal treatment across jurisdictions, and transparency about training-data provenance has become an irreversible trend.**

10.2.5 Organizational Patterns and Consulting Takeaways

Five key judgments can be drawn from this industry's transformation.

Copyright-compliance guardrails must precede the pursuit of efficiency. The Guardian and the FT chose licensing[10-22]; the NYT chose litigation[10-16]; Suno and Udio ultimately settled and paid the record labels; iQiyi's "AI Consent Form"; and the

AI protections SAG-AFTRA won through the first full-scale shutdown of 160,000 actors in 63 years — all point to the same conclusion: AI transformation in the content industry is first and foremost a renegotiation of the rights structure.

AI content labeling is a mandatory organizational variable. On September 1, 2025, the Measures for the Labeling of AI-Generated Synthetic Content (Chinese: 《人工智能生成合成内容标识办法》), issued by four ministries, took effect, requiring explicit and implicit labels on AI content — the most systematic AIGC labeling regulatory framework among the world's major economies. Douyin upgraded its labeling features in parallel, throttling, demoting, and even removing unlabeled content. Content institutions must internalize "labeling compliance" as a step in the production process.

Trust assets are a moat that cannot be outsourced. The BBC/EBU test data draw the red line of "must be human-reviewed," and "AI mass production, human review gatekeeping" remains the industry benchmark. Agents are becoming autonomous execution units within production processes — but autonomous execution does not mean no one is accountable; an accountability mechanism must be built in parallel.

The essence of human-AI division of labor is "scale to AI, meaning to humans." The practice of the four major wire services shows that AI excels at scale and speed while humans excel at human care, trust-building, and value judgment. The first question of any transformation consultation should be "which steps' scale dividends are worth capturing," not "which jobs will be replaced."

Organizational form must upgrade with strategy, and policy must precede deployment. Of the 1,000 AI initiatives across global newsrooms, nearly two-thirds are built in-house, yet only 127 have supporting policies, and only 7% directly target monetization[10-24] [third-party verified] — "fast deployment, slow policy, unresolved monetization" is the industry's common ailment. The mark of maturity for content-industry AI-native transformation is not how many AI projects were built, but the disappearance of AI-specific roles (FT), the labelability of AI content (China's regulation), and human-AI collaboration becoming the default way of working (BBC, Mango).

Copyright governance enters a "government-aligned" stage, and global standards are splitting. On September 1, 2026, the U.S. government filed in the New York court, publicly supporting OpenAI's "fair use" defense in The New York Times

case and arguing that LLM training is "highly transformative"[10-125] — the dispute has escalated from "media vs. AI company" into a policy contest of "creative-industry interests vs. national AI competitiveness." The same training data is now receiving sharply different legal treatment across jurisdictions: if the "highly transformative" theory is adopted, the licensing-negotiation balance tips markedly toward AI companies. For content institutions, the implication is that licensing cannot be governed by "one standard" globally — the more international the content distribution, the more complex the copyright compliance, and transparency about training-data provenance is becoming an irreversible trend.

Examine AI stage by stage across the production process, rather than embracing or resisting it wholesale. A new book introduced by Nieman Lab systematically examines how AI is reshaping the newsroom across five stages — story selection, sourcing, reporting and writing, editing, and distribution — concluding that the effects are for better and worse[10-152]. That process-level view is more instructive than an argument about attitudes: it translates directly into stage-level admission standards and human checkpoints for newsrooms — which stages AI genuinely speeds up, and which stages it introduces factual error, weakened sourcing, and the ceding of editorial judgment. **Organizational capability, not technology, sets the ceiling for content institutions.** TMTPost's 2026 trend outlook cites Gartner's forecast that by the end of 2026, 40% of enterprise workflows will be augmented or orchestrated by AI agents, with human employees shifting from executants to commanders and reviewers, and talent development moving from operational skills to AI trainers, prompt engineers and hybrid business-technology profiles. The article lists four items of organizational-DNA rework that executives must personally drive: rebuilding or augmenting workflows around agents; planning and managing the digital workforce (including redesigning the org chart and role definitions, and specifying human-machine boundaries and protocols); investing in AI literacy and specialized skills across the workforce; and building performance and incentive systems tied to AI contribution — warning that without solving organization and culture, the outcome is "first-rate tools, second-rate processes, third-rate results," and the upgrade stalls on internal resistance[10-173].

Role redefinition starts on the appraisal form. A study of how generative AI affects journalists' role perception proposes three progressive effects: at the operational level, AI tools reshape daily routines and skill structures; at the professional-boundary level, they trigger anxiety about job replacement, the erosion

of professional barriers and the ceding of agency; at the value-identity level, they push journalists from "information gatherers" toward "meaning interpreters." The organizational responses it prescribes are not reassurance but three concrete moves — shift appraisal from article counts and click-through rates toward depth, influence and public value (when formulaic copy can be generated at will, volume is no longer a meaningful metric); make AI literacy training routine and cultivate critical thinking and ethical judgment in human-machine collaboration; and widen career paths so journalists can move into roles such as content curators, public-issue moderators and data-narrative specialists[10-174]. **Those three moves can be copied straight into any content organization's performance framework: appraisal, training and career paths, all three required.**

The change in the "bar" is most visible in job listings. In 2026 campus recruiting at game companies, AI-related roles jumped from 45 categories in spring to 116 in autumn (82 algorithm, 31 agent, 26 large-model, 9 AIGC); across more than 7,300 open positions at 13 leading studios, AI-related roles reached 1,076, close to 15% of the total, while the "iron triangle" of programming (404), art (357), and game design (228) remains the mainstream[10-205]. The bar rose on seniority at the same time: in January–February 2026, positions requiring three or more years of experience reached 73.34%, while openings for under one year fell about 20% year on year[10-205]. **AI does not add one more category of hire; it shifts the entire seniority structure upward — the entry channel narrows while new roles cluster where production processes can be directly rebuilt.**

And adjustment precedes replacement. Industry surveys show about 30% of game workers worldwide were laid off in the past year and about 35% of companies changed their hiring intent because of AI (declining to refill some roles); notably, only about 35% of workers said they feared losing their jobs[10-206] — the article's reading is that the optimistic assumption "employment is only affected once AI fully replaces a role" underestimates what is happening. Another survey found 44% of workers considering leaving the industry because of layoffs and the spread of AI[10-207]. **Talent loss precedes efficiency gains: when experienced practitioners leave amid uncertainty, a company trying to raise output with AI has already lost the people who judge quality.**

The center of gravity in copyright disputes is shifting. China's Supreme People's Court issued no unified rule on the copyrightability of AI-generated content, citing the absence of consensus in theory and practice and the lack of any global

standard, so practice has turned to training-data use, platform liability, and content compliance[10-208]. Industry observers note that disputes have spread from the "model training side" to the "content generation side" — AI engines directly aggregating or reworking original sources, draining traffic from creators — with defense shifting from litigation toward "how to get your content correctly cited and presented"[10-209]. On the US side, the Copyright Office's copyrightability report and a series of registration cases strike the same floor: "human-led creation" remains the key to registration. **That means "at which step a human intervened and what trace they left" now carries legal significance; creation intent, revision history, and the licensing chain for AIGC assets must be recorded — a process change, not a tool purchase.**

The real state of newsrooms this year is not a replacement story. Editors Weblog's annual stocktake concludes that the reality in 2026 is pressure, speed, and uneven adoption producing both real risk and real efficiency at once, with the gap between newsrooms showing up in depth of adoption rather than in whether AI is used[10-210]. This matches the four gaps (strategy, audience trust, capability, skills) in the companion *Future Newsrooms Study 2026* (448 newsroom leaders across 86 countries) — the bottleneck is attributed to people and organization, not model capability. **For publishers and media organizations, the management implication is that AI programs must be designed alongside editorial decision processes, role skills, and quality-control mechanisms; otherwise the efficiency stays confined to a few isolated steps. The most important organizational change in the content industry this year is rights holders shifting from "defending copyright" to "operating an AI ecosystem."** Within a year, AI music licensing flipped from courtroom confrontation to mainstream deals: in October 2025, Spotify and UMG, Sony, Warner, Merlin, and Believe announced an "artist-first" AI product; in November, Universal settled with Udio and announced the first licensed AI music platform, KLAY became the first AI company licensed by all three major labels (including Sony), and Warner settled with both Suno and Udio; in 2026, Merlin and Kobalt each signed with Udio[10-240]. The common institutional feature of these deals is artist opt-in — the default state of any catalog is "unlicensed." Alongside this comes capability internalization: Warner Music opened a technology and engineering center in Bengaluru, India, in September 2026 to drive "core business-critical architecture, AI capabilities, and global systems," in tandem with outbound licensing. **The strategic split is equally clear**: Netflix acquired

InterPositive outright (no licensing, no revenue sharing) to fully own the AI production technology, while Disney signed a licensing deal with OpenAI's Sora platform — "controlled access rather than full ownership"[10-241]; build/own versus buy/license is the same fork seen in law firms and logistics. **But a rising AI revenue share is not the same as realized value**: at the ad-holding group Publicis, AI-supported functions already account for more than 85% of net revenue (rising to 87% in Q2 2026), with consecutive growth and a record 17.5% first-half operating margin — and its CEO simultaneously admits that AI is "hard to scale, costly to land, and in 95% of cases delivers no measurable value"[10-242]. **It is rare for a top-group executive to keep "AI revenue share" and "AI actual value" as two separate books — this is the pair of accounts to read side by side when judging the pace of content-industry AI commercialization.**

The framing of layoffs is itself changing. More and more senior executives at large tech companies publicly name AI when explaining layoffs, and analysts note this also signals investors: faced with AI development costs that are real and enormous, distinguishing "the reason of technical transformation" (long-term, mapping to process and role redesign) from "the reason of financial discipline" (short-term, mapping to cost restructuring) matters, because the two require entirely different responses[10-286]. The opposite over-simplification deserves equal caution — the popular "one-person company" narrative omits its boundary conditions: tools replace capacity, not responsibility for markets and risk[10-287]. **When reading AI keywords in this industry, the first move is to separate "because of AI" from "happened at the same time as AI."**

10.3 Financial Services

10.3.1 Industry Profile and Bottleneck Triage

The head-office report of a state-owned big bank reads "AI replaced 15.56 million hours of human work," but down at the second-tier municipal branch, the branch manager cannot say what AI actually changed — this is the most truthful picture of banking in 2026: the numbers on the reports look great, the feel on the frontline is weak[10-35] [third-party verified]. Someone put the gap vividly: they gave the carriage a better whip instead of swapping it for a car.

Finance is a quintessentially information-intensive industry: a credit decision, a research report, a claims settlement — all are information processing at bottom, with an information-to-physical bottleneck ratio of about 80:20. Tencent Research Institute ranks it among the best scenarios for large-model deployment; McKinsey estimates that generative AI could create US$200 billion to US$340 billion in value for the global banking industry each year — 2.8%–4.7% of the industry's annual revenue[10-32]. But fertile soil is not the same as easy plowing; three core contradictions stand in the way.

Heavy regulation comes first. Credit scoring, anti-money laundering, and underwriting are classified as "high risk" under the EU's AI Act[10-34], and China's National Financial Regulatory Administration has also issued guidance on AI application in banking and insurance[10-33], requiring full-lifecycle model management and explainability. Second is data sensitivity: customer privacy, transaction data, and model hallucination are directly tied to capital and reputational risk — the warning from Gu Shu, chairman of the Agricultural Bank of China, at the Lujiazui Forum (model black boxes, hallucination, and the uncertainty of autonomous decisions) represents industry consensus. Third is organizational inertia: IBM research shows that as of 2024, only 8% of banks were systematically developing AI while 78% still used tactical, fragmented approaches [third-party verified]. Finance does not lack AI enthusiasm; what it lacks is the organizational capability to turn pilots into systems.

10.3.2 Transformation Paths and Typical Practices

Banks, insurers, and brokerages have taken three clearly differentiated paths.

Banks are highly stratified internally. The big state-owned banks pursue a "model matrix plus compute infrastructure" route: ICBC's (Chinese: 工商银行) Zhirong (Chinese: 工银智涌) hundred-billion-parameter financial large model empowers 20-plus business areas and 200-plus scenarios, with AI digital employees handling the equivalent of 55,000 person-years of work each year. The joint-stock banks focus on scenario deepening: China Merchants Bank's (Chinese: 招商银行) "AI Xiaozhao" (Chinese: AI 小招) serves more than 20 million customers a month and had AI replace 15.56 million hours of human work over the year[10-35]; Industrial Bank's (Chinese: 兴业银行) agent platform hosts more than 200 agents. The internet banks take the most thorough AI-native route: WeBank (Chinese: 微众银行) proposes "embedding the process into AI" rather than "embedding AI into the process,"[10-25] and MYbank (Chinese: 网商银行) uses three AI systems — Shanque (Chinese: 大山雀), Dayan (Chinese: 大雁), and Bailing (Chinese: 百灵) — to rebuild micro and SME lending.

DeepSeek's open-sourcing in 2025 triggered a wave of local deployment: 20-plus financial institutions completed private deployments at million-yuan-level cost, breaking the pattern of "financial AI belongs only to big banks."

Insurance is penetrating along the full value chain — product pricing, marketing and customer acquisition, underwriting, claims, customer service, and operations are all landing, with knowledge-intensive steps such as agent training and claims-report writing benefiting first. Brokerages have made investment research their main battlefield: large-model adoption in the securities industry reached 26.7%, and investment research is the field most likely to first achieve an end-to-end "data-research-investment-risk control" chain.

On organizational change, two routes diverge sharply. JPMorgan Chase chose retraining and flexible transition — employees shift from "makers" to "checkers" (managing AI agents)[10-27]; Standard Chartered, by contrast, announced it will cut more than 15% of corporate-function roles (about 8,000 people) before 2030, with the CEO bluntly saying these roles are "giving way to machines." DBS runs a dual track of "AI replacement plus AI role creation," committing to hire about 1,000 AI roles; China's six largest banks saw total headcount at end-2025 rise by just 1,538 people, yet tech talent grew by a net 35,000 to 135,900 — the structural blood transfusion is already visible to the naked eye. How financial sub-sectors buy AI draws the in-house-versus-outsourced division clearly. Zero One Think Tank reviewed public tender data for financial agents from January 1 to June 15, 2026 (97 de-duplicated valid samples): banks (including rural credit cooperatives) accounted for 47 notices, or 48.5%, with securities at 14 and insurance at 12 — together more than three quarters. Building a unified agent application/development platform became an industry-wide consensus, yet platform purchases fell from over 60% in 2025 to about 28.9%, as scenario-specific applications spread across the board (risk and compliance 19.6%, marketing and customer service 11.3%). The layering is clear: the large state-owned banks and leading joint-stock banks generally build their own core agent foundation (only three tenders were observed from large state-owned banks in the period, all for specific scenarios or custom projects), while smaller banks and non-bank institutions — securities, insurance, financial leasing — buy mature platforms and vertical-scenario agents. Bank of Suzhou released six purchases at once, building an enterprise platform with a closed loop of lending review, post-loan management, intelligent approval and credit due diligence agents; Bank of Ningbo landed nine projects in six months; Industrial Bank procured a data-center AI agent (predictive maintenance,

intelligent alerting, troubleshooting, energy optimization) and a retail-marketing agent[10-175]. **One detail deserves attention: several insurance institutions procured AI agent training courses and organizational-change support services — the industry is starting to treat "organizational readiness" as part of the deliverable rather than a soft bonus after go-live.**

Brokerages are splitting into two paths at the same time. One, represented by GF Securities (Chinese: 广发证券), plugs into general-purpose agents to focus on office collaboration and process efficiency — solving the "efficiency problem." The other, represented by Zhongtai Securities (Chinese: 中泰证券), co-develops agents with vertical model companies and cuts deep into core investment research and advisory work — solving the "professional productivity problem." FinStep (财跃星辰, incubated by Jiemian Cailianshe and StepFun) illustrates the second path: at the Bund Conference it launched a product matrix spanning the consumer-side "Xiaocaishen" assistant, CashClaw scenario tools and the institutional Finwork advisory assistant, co-built a multi-agent investment research platform with Zhongtai Securities, and open-sourced the Alpha-R1 financial reasoning model with Antai College of Economics and Management at Shanghai Jiao Tong University. Its CEO describes the route as validating "trusted sources, controllable outputs" on the consumer side first, then pushing the capability back into B2B institutions so that agents are embedded in business processes rather than left at the tool layer[10-179]. **To judge whether a financial institution is becoming AI-native, ask what it bought: a tool that improves efficiency, or a colleague that changes processes.**

10.3.3 Benchmark Cases

WeBank: the most complete sample of an AI-native organization. [official claims + third-party verified] WeBank proposed the move "from digital-native to AI-native" in 2023, defined as "not AI embedded into the process, but the process embedded into AI." The implementation mechanism has three layers: an AI infrastructure layer (an engineering platform where compute is allocatable, models are pluggable, and outcomes are measurable, supporting private deployment of open-source models such as DeepSeek), an AI application layer (70-plus digital employees and more than 800 agents covering over a thousand business scenarios), and an AI governance layer. By end-2025, AI compute had grown 3.5x year over year and daily call volume had risen from 41,000 to 2.4 million[10-26] [official claims]. Organizationally, it established technology product managers to coordinate technology planning,

breaking the old "business raises requirements, technology executes" model; in budgeting, it uses the "Innovate the Bank" program to invest ahead in frontier technology and allow room for trial and error. This is the most complete sample of AI-native organizational change among domestic banks.

JPMorgan Chase: methodology at scale. [third-party verified; benefit figures per the CEO's public statements] 450 production-grade use cases[10-28], with the AI professional team growing from 1,500 people in 2022 to 2,500+. The methodology: use cases must be bound to business KPIs rather than technical metrics; human-AI collaboration is designed in rather than full automation; data governance and model risk management come first; start from high-value, low-risk scenarios such as document processing and code generation, then expand into customer interaction. In 2025 it spent US$18 billion on technology, about US$2 billion of it on AI; CEO Jamie Dimon said the firm "spent US$2 billion and got about US$2 billion in benefit"[10-27] [official claims], positioning AI as a "do-or-die" strategic investment.

DBS: a pioneer in AI value accounting. [official claims + third-party verified] DBS has deployed more than 1,500 AI models across 370-plus scenarios, creating S$1 billion (about US$750 million) in AI value in 2025[10-29] and being named "World's Best AI Bank" by Global Finance. Its key practice: every year it transparently measures AI value along three dimensions — revenue uplift, cost savings, and risk avoidance — and sets investment priorities accordingly. Directly linking AI investment to financial output is the critical infrastructure of AI-native organization management.

SPD Bank: AI moves from "storytelling" into the income statement. [third-party verified] SPD Bank's (Chinese: 浦发银行) 2026 interim report discloses more than 440 AI applications built and 220 agents deployed in production, spanning smart marketing, smart operations, efficient operations, digital risk control, and intelligent management; within the year it launched the "Puyin Zhizhi" (Chinese: 浦银智启) model-service matrix, was among the first to deploy GLM 5.1 and DeepSeek-V4, and built three flagship financial verticals in form recognition, financial analysis, and industry analysis[10-126]. Listed banks are writing "number of deployed agents" and "vertical-model applications" into their periodic reports — the "equivalent headcount of digital employees" has become an annual-report-level disclosure metric, meaning AI is entering the bank's formal operating and performance language.

H1 reports from 42 listed banks put agents into mandatory disclosure. [third-party] A China Business Journal review of 42 listed banks' H1 2026 reports finds that, as of the end of June, ICBC's large model had gone live in more than 600 scenarios; China Construction Bank and China Merchants Bank each deployed 256 domain models (up 40% from the end of last year); Ping An Bank had landed more than 450 large-model use cases and launched 140 operations-review agents in the first half (covering AML due diligence, account review, fund settlement, and cross-border remittance, with consumer-protection review intelligence coverage above 90%); Bank of Nanjing's dual-hundred plan brought its cumulative total to 156 business agents; and ICBC's AI review agent output 360,000 compliance-review opinions in the first half with a 98.6% adoption rate, lifting the risk-identification capability of compliance reviewers by 130%[10-153]. The measurement difficulties disclosed alongside are just as noteworthy: AI returns are hard to attribute across periods, risk-side returns appear as losses that did not happen and therefore never reach the income statement, and token costs are non-linear — China Merchants Bank disclosed its AI contribution ratio improving from 1:13.5 at the end of 2025 to close to 1:9 in May 2026. **Once agent counts become an annual-report metric, the competitive focus shifts from whether you are doing it to whether you can account for it.**

10.3.4 Failure Warnings

Jane Street's US$15 billion loss. [third-party verified] In July 2026, quant giant Jane Street suffered a single-month loss of nearly US$15 billion[10-30] — its first monthly loss in about a decade — partly attributable to a sharp drawdown at Situational Awareness, an AI hedge fund it invested in, compounded by wrong directional bets on Asian stocks; in the same period, the AI stock selloff triggered cascades of margin calls at Goldman Sachs and JPMorgan. There is a vast gap between the "AI stock god" narrative and real risk: AI capability amplifies tail risk, and model extrapolation and concentration risk do not disappear just because the machine is "intelligent."

Klarna's pullback. [third-party verified / CEO public interview] Klarna cut its workforce from more than 7,000 people to under 3,000, with AI handling 2.3 million conversations a month — the workload of 700 full-time customer service agents[10-31]. But in May 2025 the CEO publicly admitted the company had "gone too far": the excessive pursuit of efficiency degraded service quality, forcing a shift to the "Uber model" — AI handles standard questions while humans handle interactions that need

emotional connection, and NPS and satisfaction recovered accordingly. Two lessons: AI customer service must read the original business code rather than FAQs; and "AI can answer" does not equal "AI can solve the problem" — technical metrics and business metrics can decouple.

The frontline temperature gap: statistics versus on-the-ground reality. [third-party verified] The six largest banks spend 130.091 billion yuan a year on fintech[10-36], with cumulative industry investment approaching one trillion yuan — yet the "feel" at second-tier municipal branches remains weak: AI applications are still mostly "point-wise embedding" and have not yet penetrated to bottom-level reconstruction of business processes. Some city commercial banks even prohibit using AI to generate discussion materials. Value metrics such as "person-years," "work hours," and "scenario counts" are not interoperable with each other, frontline employees are turning into "AI trainers" (data labeling, feedback, scenario training), and "saving 15.56 million hours" is more about avoiding headcount increases than directly cashing out headcount reductions.

10.3.5 Organizational Patterns and Consulting Takeaways

Regulation first determines the order of landing. The rollout sequence of financial AI applications is determined not by technical difficulty but by regulatory tolerance: intelligent customer service, document processing, and code generation go first, while core decision-making links — credit approval, asset pricing, capital trading — must wait for the governance framework to mature. The EU AI Act requires high-risk financial AI to meet compliance by August 2026 (violators face fines of up to 7% of global turnover)[10-34], and the NFRA guidance requires AI risk to be folded into the comprehensive risk-management system[10-33] — compliance is not an obstacle to transformation but its roadmap.

Data governance is a precondition, not an afterthought. Model hallucination in financial scenarios is a business accident, not a technical failure; discriminatory bias in historical data gets institutionalized through models. The first step of any consultation: build the model registry, risk grading, and human oversight mechanisms before talking about scale.

Talent-structure change is harder to manage than technological change. Foreign banks are densely establishing Chief AI Officer roles (an IBM survey shows the share of organizations with a CAIO jumping from 26% to 76%); yet Standard

Chartered's former CAIO considers the role "rather short-lived" — "as AI becomes a tool like Excel." Organizational form is evolving toward a "pine tree" (the view of the CIO of Evergrowing Bank, Chinese: 恒丰银行): a small number of core decision nodes support large-scale standardized execution, and middle management gets compressed. On talent strategy, the dual track of "replacement + role creation" is more sustainable than pure layoffs: retained staff see salaries rise (Klarna's average pay rose nearly 50%[10-31]), and transferred staff move into data and scenario-training roles.

Value accounting moves from "comparing input" to "comparing real outcomes." After cumulative industry investment approaching one trillion yuan[10-36], the bank AI race has entered its "calculating ROI" second half; establishing a unified AI value-measurement system (the DBS three-dimension method being a reference) should be a consultant's first move. The AI-native transformation of finance has never been a technology-selection problem; it is an organizational problem of re-arranging four things in parallel: the regulatory framework, data governance, talent structure, and financial accounting.

Scaling is an evaluation-and-governance problem, not a model problem. The OpenAI–Morgan Stanley case shows adoption of the wealth-management AI assistant approaching 98%; the key was not the model but the "evals system" — quality and compliance evaluation standards customized for financial scenarios, with models continuously validated before and after deployment, which is what made it safe to expand from pilot to all staff in a heavily regulated industry[10-127] [official claims]. EY's AI Bank white paper supplies the counter-evidence: about 60–70% of banks still cannot replicate AI across business lines after completing more than ten pilots; over half of AI projects stall at the pilot stage, mainly because business and technology are disconnected; high-return banks staff their AI teams with 40–50% people from business backgrounds, and a mature AI talent system shortens project launch cycles by 30–50%[10-128]. The watershed for financial AI scaling is not technical maturity but governance maturity and talent mix — between "pilot" and "replication" sits a closed loop of evaluation, feedback, and governance.

The organizational prerequisites for scale: agent identity, supervision, and verification. Accenture's *Top Banking Trends 2026* judges that banks will use agentic AI at far greater scale in 2026, turning to large cloud platforms to build agents that fit their own brand, compliance, and service standards. On the data side, 57% of bank executives expect AI agents to be fully embedded in risk, compliance, and audit

functions as well as fraud detection and transaction monitoring within three years, and 56% expect broad adoption in credit assessment, loan processing, and KYC; McKinsey estimates AI adoption can deliver up to a 20% net cost reduction for banks. As for cases, BNY is reinvesting in AI with plans for 150 AI capabilities and an in-house platform, Eliza, that lets employees design AI agents and integrate supervised digital workers. Organizationally, nearly half of banks and insurers are creating new roles to supervise AI agents, and most CIOs expect agents to run under centralized governance with real-time monitoring and multi-agent verification, leading Accenture to recommend an agent identity framework (authentication, authorization, entitlements)[10-154] [third-party verified]. Lloyds Banking Group, meanwhile, publicly endorses the institutional position that 2026 is the turning point at which agentic AI moves from experimentation to enterprise-wide deployment[10-155] [official claims: institutional view]. **AI will not deliver cognitive equality; it amplifies the cognition gap.** Cailianshe's report from the 2026 China Financial Markets AI Investment Research Summit puts it bluntly: AI executes instructions efficiently but will not interrogate the ambiguity behind them, so two people with different cognitive depth using the same tools see their gap multiplied — which makes "human-machine collaboration capability" the core competency, not "knowing how to use AI." The prevailing pattern is a hybrid of "AI diverges, mathematics converges": AI spreads across research and information coverage while verifiable mathematical models converge on conclusions; the radical route of rebuilding the entire process around multiple agents remains cautious territory because its process is a black box with insufficient explainability. Southern Fund's split is worth noting too: on the research side, work can almost entirely go to AI, with human value concentrating on strategic judgment and information beyond public sources; on the investment side, humans and machines each have strengths, and client companionship and emotional value remain a human fortress[10-177]. **AI is suited to standardized judgments with abundant, repeatedly verifiable samples; the human edge is recognizing when a historical regularity has stopped working, and coping with extreme uncertainty that has no historical precedent.**

Results in process-type scenarios cannot be extrapolated to decision-type scenarios. IDC China's financial-industry agent best-practice review draws the boundary clearly: the biggest change is that agents go from tools to "business partners" that perceive, decide, act and remember, and insurance and asset management have moved from proof of concept into vertical-scenario innovation; but

current deployments cluster in process-type work, where the effects are cost reduction, efficiency and process improvement, while genuine "high-autonomy decision-making" remains exploratory. IDC expects that as autonomous AI matures, agents will move from assisting tools to decision participants and the payoff will shift from "efficiency gains" to "decision gains"[10-178]. **That sentence belongs in every financial AI acceptance standard: make process-type results solid before claiming decision-type benefits — using the former's numbers to prove the latter is the most common sleight of hand in financial AI business cases.**

The two paths of bank agentification now have names. Deloitte China's analysis splits how banks pursue an agentic leap into two categories. The first is "Smart Overlay": without rebuilding core systems, an intelligent conversation-and-execution layer is overlaid on legacy systems through APIs and protocols such as MCP — for example, upgrading routine clearing RPA in treasury into a dynamic liquidity optimizer capable of autonomous pricing and hedging decisions. The second is "Agentic by Design," where agents are embedded into the IT architecture as first-class citizens; its multi-agent KYC system has one agent pulling public data, one scoring risk, and one filing regulatory updates, with almost no human involvement but built-in audit trails and intervention checkpoints[10-211]. The report's conclusion is organizational: full agent deployment requires "a fundamental redesign of existing processes and working mechanisms," not simply model integration.

In the same period, asset and insurance-asset managers offered another template for "no point tools." At the 2026 China Banking, Insurance and Asset Management Forum, ICBC Wealth Management (Chinese: 工银理财) framed its AI transformation as three things: building a unified AI interaction entry point, building a matrix of "super agents plus specialist agents," and making legacy business systems AI-native, while drawing explicit lines of human-machine division — "AI assists analysis, seeing fast and calculating clearly; people make decisions, thinking deep and deciding precisely; systems execute, executing steadily and under control." The efficiency contrast is concrete: an industry weekly report that took a researcher three to four hours now takes an agent minutes to produce with multi-dimensional data, charts, and analytical judgment. Xinhua Asset Management described the same approach as three layers: a digital foundation (breaking internal silos, aggregating multi-source data) → an agent system (a "digital investment-research and risk-control team available on demand") → full-scenario applications. In the same discussion, institutions also listed AI itself as a new source of risk (model hallucination, open-

source supply-chain security) and treated "bringing AI into the comprehensive risk-management framework" as a precondition[10-212]. **Large financial institutions are converging: build the unified entry point and agent matrix first, then adapt processes and boundaries of division — which is precisely the watershed between "AI-native" and "an AI project."**

Trustworthiness is also being quantified. At the 2026 Bund Summit forum on trustworthy AI and financial agents, Ant Shengxin (Chinese: 蚂蚁胜信) disclosed the scale deployment of insurance "two-core" operations (underwriting and claims): because tolerance for error is extremely low and hallucination causes direct financial loss, it adopted an end-to-end agentic architecture with self-distilled skills, and on a baseline of 97%+ underwriting accuracy and 98%+ claims accuracy it handles tens of millions of consultations and close to ten million claims a year. Fudan's Qi Yuan offered a cooler assessment: only about 5% of enterprise AI currently translates into business value, and competition is focusing on "knowledge, reasoning, action, and governance infrastructure"[10-213]. **These numbers explain why financial agents cluster in low-to-medium-risk, measurable steps — not for lack of ambition, but because in settings where hallucination equals direct financial loss, trustworthiness has to be proven before scaling even begins. The turning point on the securities side is "from building in-house for internal use to opening an ecosystem."** 2026 is seen in the industry as the "year of financial agents": in mid-September Moonshot AI released a Kimi solution for the financial industry (entering core business processes with "authoritative data sources + professional skills + security compliance"), and dozens of top institutions including ICBC, CITIC Securities, CICC, and E Fund have landed or co-built with it; in early September Tencent WorkBuddy's financial edition launched, with GF Securities the first licensed broker to connect. Brokers' own moves shifted from point improvements to system rebuilding: Huatai Securities began "ALL IN AI" in 2023 and launched "AI Zhangle," an AI-native app focused on trading; Guotai Haitong iterated "Lingxi App 3.0"; China Merchants Securities built "AI + customer service" and "AI + business operations"; CICC systematically advanced a "client-agent, advisor-assistant-agent, wealth digital employee" agent group[10-243]. **The keyword in half-year reports shifted from "cost reduction" to "capability rebuilding" — the center of gravity in financial institutions has moved from "doing AI projects" to "redesigning roles and systems around AI."** Running in the same direction is the large-scale "onboarding" of digital employees: *Beijing News* distilled four signals — the

global AI digital-employee market will exceed RMB 46.9 billion in 2026, with China at 31.56%; 72% of enterprises have completed agent pilots and put them into formal use, deploying across 3.5 scenarios on average and planning to reach 6.7; the "large model + Agent + RPA" three-layer architecture has taken shape; Gartner predicts 40% of enterprise apps will embed task-specific agents by 2026, and Zhaopin data shows 10.3% of workplace respondents' employers have formally deployed "digital employees"[10-246]. **Once digital employees enter the HR management scope, the organization must extend from "managing people" to "managing people + managing AI employees" — with clear duties, permissions, and assessment standards, not treated as an advanced search box.**

The flip side of the "year of agents" is that definitions are harder to unify than numbers. The middle tier offers a "boutique" path rather than piles of count: Jiangsu Bank's "1860" system uses 1 unified intelligence base, 8 "digital tellers" assisting 8 role types, and 60 high-value scenarios, with the core idea of "AI Inside" (AI as an assistant, not replacing human professional judgment); Ningbo Bank concentrated on 5 bank-wide core agents in 2026, each a closed-loop design. A reminder from the Agricultural Bank chairman at the Lujiazui Forum is repeatedly quoted: "Some banks say a few hundred agents, some say tens of thousands — the counting standards differ enormously; the key is still the actual business result"[10-245]. Huawei's *Digital Employee 3.0* white paper structures the paradigm change: in the traditional "+AI" model — embedding AI functions into existing processes — AI is an adjunct to the process; generative AI pushes a shift to "AI+" — redesigning the entire business process and interaction around AI, making AI the "orchestration and collaboration hub," and giving each employee multiple "digital twins" to form a new intelligent team of "1 human + N digital employees"[10-244]. **Consultancies and vendors converge on the same sentence: an AI-native bank's competitiveness comes from systemic rebuilding of technology and operating models, not the stacking of point projects** — Bain ties "AI-native modern bank" directly to the issues of "technology operating model" and "people and organization"[10-248]. IBM adds the management side: performance measurement must "include cost-effectiveness" (matching model complexity to the task, tracking agent ROI), and "even when AI makes decisions, humans design the system and are responsible for its output"; its forecast is a slower, bounded fusion — "even if AI systems can do 90% of human work, the remaining 10% will be the hardest part to automate yet"[10-247].

Occupation-level evidence is becoming concrete. The UK Financial Services Skills Commission reports that some roles shrink relatively and that **the foundation of entry-level roles is damaged by AI, which may weaken the talent pipeline** — so beyond reskilling, what is needed is redesigning roles and progression paths[10-288]. A banking digitalization research outfit lists the new job families — agent operations lead, model governance officer, AI risk underwriter, decisioning systems architect: these are not "more senior versions of old jobs" but a new shape in which multiple agents, multiple data sources and multiple stakeholders are orchestrated into one coherent output, and most banks have the reskilling direction backwards — not training existing staff to do the same work faster, but redesigning what people should do[10-289]. On the Chinese side, a joint assessment by the Shanghai Advanced Institute of Finance and the Ant Group Research Institute concludes that in 2026 the global AI industry has fully entered a phase centered on application deployment and commercial closure[10-290]. **Together the two sets imply that the acceptance test for a financial institution's transformation is not "how many people were trained" but "how many new roles were defined."**

The six largest banks have moved their language from "install systems" to "change the mode of production." A 2026 review of the six state-owned banks groups their dense upgrades under a single line: models moving from the substrate to the front office, agents moving from Q&A tools to task execution, and data governance, security mechanisms and talent/organization building accelerating in step. Architecturally, ICBC proposes "AI-ICBC," with an "ICBC Zhiyong" technology base, an "ICBC Data Treasury" data space and three digital platforms (corporate, retail, employee) forming a "1+1+3" system; ABC is deepening AI-native applications and building "service-as-conversation"; CCB is advancing AI-native agent applications; PSBC proposes an autonomous, controllable AI-native technology architecture and a "Data for AI" program building a "1+3+6+N" high-quality dataset system (more than 60,000 multimodal items intelligently labeled, over 28 million high-quality records accumulated); Bank of China completed "Zhilan" 1.0, setting a unified bank-wide data architecture around collection, storage, construction, use and management; Bank of Communications proposes AI-native products, services and operating models. The definition worth quoting in full: for a bank, AI-native means "not one more AI department or AI feature, but a fundamental reconstruction of the mode of production, requiring technology architecture, business processes, organizational form and strategic culture all to be redesigned with AI capability as the first principle"[10-313].

That wording explains where bank AI budgets end up: the money flows into data governance, because the first brick of "first-principles redesign" is a unified definition of terms.

10.4 Education

10.4.1 Industry Profile and Bottleneck Triage

In May 2025, Chegg — once valued at US$12 billion — announced layoffs of 22% [10-44]: the education unicorn built on "homework help plus textbook rental" saw its business model directly commoditized by free general-purpose AI such as ChatGPT [third-party verified]. Almost simultaneously, a randomized controlled trial at Georgia State University (GSU) showed that an unassuming conversational chatbot lifted first-generation students' final grades by an average of 11 points[10-37] [third-party verified]. Collapse on one side, evidence on the other — the education industry's AI era cracked open exactly like this.

Education is a typical "dual information-physical bottleneck" industry, with an information-to-physical ratio of about 70:30. Knowledge instruction, homework grading, Q&A and assessment, and admissions administration are all information processing — the most direct use case for large models; yet the underlying mechanisms of learning outcomes — motivation, focus, peer encouragement, and teacher-student trust — still depend on in-person settings and human presence. This yields the first core contradiction: teaching delivery can be productized, but the in-person experience is hard to replace. The second is the double-edged sword of fairness: AI can amplify quality teaching resources at extremely low cost, but unequal access can widen the digital divide — GSU used AI to raise disadvantaged students' grades, while LAUSD's high-profile AI project collapsed precisely in the district with the deepest digital divide. The third is the tug-of-war between AI literacy and dependency: China lists teachers' digital literacy as a "basic item" of transformation, the EU's AI Act turns AI literacy into a legal obligation, and students using free general-purpose AI to replace paid services are in turn forcing the industry to redefine "what learning cannot be outsourced."

10.4.2 Transformation Paths and Typical Practices

Four paths are advancing in parallel.

Universities' organizational transformation came first. In January 2024, Arizona State University (ASU) became the world's first university to fully partner with OpenAI, embedding ChatGPT into teaching, research, and administration across the board; OpenAI subsequently released ChatGPT Edu for higher education, turning universities into institutional clients. GSU embedded AI into the "student success" chain of early warning, reminders, and intervention. By end-2025, industry discourse had shifted from "using AI tools" to the "AI-native university," with AI beginning to embed into the full chain of admissions, teaching, administration, and governance. Yet Ithaka S+R's interviews with 246 faculty members at 17 U.S. and Canadian universities show that many faculty are unaware of the AI resources their own schools already have — the bottleneck is not technology but organizational communication and trust [third-party verified].

The evidence for AI tutors is accumulating. A review in the Education Next forum offers balanced evidence: when expert teaching decisions are injected into GPT-4, its math responses were rated "good" by humans 76% of the time (the Bridge approach), and AI-tutored students completed in 49 minutes what a control group covered in a 60-minute lecture; but the researchers also warn that publication bias is widespread, and most online math programs show minimal gains for "95% of students."

The divergence among education companies is now clear. Duolingo maintains high growth through AI-driven course generation and personalization[10-48]; Youdao (Chinese: 网易有道), built on its "Zi Yue" (Chinese: 子曰) large model, has repositioned its brand as a "learning and advertising AI application service provider," with AI subscription sales surpassing 100 million yuan in Q1 2026 (+70% year over year) and online marketing revenue overtaking its traditional education business for the first time; Squirrel AI (Chinese: 松鼠Ai), which started with adaptive algorithms, had its intelligent adaptive system named to TIME's 2025 Best Inventions; New Oriental launched "AI 1-on-1," and Zuoyebang is betting on large-model learning devices. AI-native organizations earn a growth premium; slow transformers slide into structural decline.

China's policy path is entirely different from the West's: the West runs institution-driven pilots, while China is "state-driven, top-down, scaled landing." In March 2025 the Ministry of Education deployed the "AI and Education Reform" strategic action 2.0; in April, nine departments issued the Opinions on Accelerating the Digitalization of Education (Chinese: 《关于加快推进教育数字化的意见》); in April 2026, five departments jointly issued the "AI + Education" Action Plan[10-46] (Chinese: 《"人工智能+教育"行动计

划》), proposing to form a deeply integrated AI-education pattern and popularize AI education in primary and secondary schools by 2030 — elevating AI from an "informatization tool" to a "force for systemic reconstruction." The EU has taken a third path: the AI Act classifies grading, admissions, and assessment education AI as high risk, mandating human oversight and AI literacy training — regulation shaping organizations in reverse.

The latest baseline on the university side comes from EDUCAUSE: a survey run with AIR, NACUBO, and CUPA-HR that collected 1,960 valid responses found that 81% of respondents felt enthusiastic about AI or cautious and enthusiastic at once, while only 17% were cautious or very cautious; 92% of institutions already had a work-related AI strategy (most commonly piloting AI tools, assessing opportunities and risks, encouraging faculty and staff use, and setting policy and guidelines), and among institutions that included upskilling in their strategy, most did so by providing training and support[10-156] [third-party verified]. **The value of this data is that it expands the higher-education AI conversation from student cheating to institutional operations and staff work — organizational readiness is the real weak point in university AI strategy.** The deployment list in higher education is already long, though maturity is clearly layered. EDUCAUSE's 2026 report shows about 74% of U.S. institutions have at least one production-grade AI deployment that directly affects students, with AI teaching assistants and faculty research support the most mature and conversational student feedback the fastest growing; the landing zones cluster into six areas — admissions and applicant processing, academic advising and student success, course-level AI teaching assistants, academic-integrity policy, faculty research and grant support, and student feedback collection. The long-running benchmark is Georgia State University's Pounce, answering applicant and student questions since 2016 and initially credited with cutting the "summer melt" rate (admitted students who never enroll) by about 21% in a randomized field study by Lindsay Page and Hunter Gehlbach; the same technology stack has since handled millions of student messages, shifting adviser capacity to complex cases. Among course-level assistants, the most cited is Harvard's CS50 Duck, which answered more than 800,000 student questions in 2024-2025 and is configured to teach through Socratic questioning rather than handing over code answers[10-180]. **What these cases share is not a superior model but placement inside a process with an accountable owner — an AI teaching assistant succeeds only when a course, a person and an assessment change along with it.**

10.4.3 Benchmark Cases

Georgia State University's Pounce: embedding AI into the "student success" process. [third-party verified] Pounce is the most evidence-robust AI application in education: in its first summer it interacted with incoming freshmen 185,000 times[10-38]; a randomized controlled trial showed that students who received conversational reminders lifted their FAFSA completion rate and fall enrollment rate by 3 percentage points and cut fee-related dropout by 50%; the classroom version of the chatbot raised the share of students earning a B or better in an introductory political science course by 16 percentage points versus the control group[10-37]. The key is not the model but the organizational design: AI does not replace teachers; it scales advisory services at extremely low cost.

Duolingo: the growth premium and organizational cost of being AI-native. [third-party verified] Its personalization engine, Birdbrain, has been running for more than a decade; on April 30, 2025, the company used AI to generate 148 courses in a single day, doubling its course catalog outright. The financial results are striking: 2025 full-year revenue of US$1.038 billion (+39%) and 52.7 million DAU (+30%)[10-48]. But a leaked "AI-first" internal memo in May 2025 triggered a public backlash, Q2 growth fell from 60% to 40%, and the stock dropped from its high of US$544.93 to about US$95 by March 2026 — going AI-native delivers a growth premium while also amplifying the communication and capital risks of organizational change.

Khan Academy: AI tutor iteration driven by an experimental culture. [official claims] Between October 2025 and April 2026, the Khanmigo team ran systematic product experiments across more than 15 million tutoring sessions: structuring students' recent problem-solving history for the model lifted the "next-question correct rate" by 6.1%; simplifying model output cut average response time by 3 seconds while math accuracy held steady; and adding session records from within 24 hours lifted cognitive engagement by 5.09%[10-39]. The organization candidly admits "no single improvement brings a leap," but combined optimization significantly improves results while lowering costs — this is the core engineering capability of an education AI-native organization: an experimental culture plus scaled A/B testing. **CUHK-Shenzhen: making agents a university-wide public infrastructure [official claims]** — its Information Technology Services Office has published an "AI Agent" program spanning teaching, research and administration and delivering an

integrated "AI teaching assistant, AI research assistant, AI administrative assistant" service. Teaching covers course-resource generation, lesson-plan optimization, assisted item writing, classroom interaction support and learning analytics; research covers literature search and review, idea generation, project-material organization, data analysis and grant applications; administration covers policy Q&A, document drafting, process guidance and knowledge-base building. The stated goal is "four unifications": a unified entry point, unified capabilities (large models, knowledge bases, business systems and AI applications), unified standards (data security, content compliance, permission management and application standards) and a unified ecosystem — the end state being "one platform, many kinds of agents, all scenarios enabled"[10-182]. **Compared with departments buying tools on their own, a university-level platform solves for concentrating capability and governance at the same time — the organizational form of the AI-native university.**

A reusable governance framework for education agents is emerging. CAICT's *2026 Enterprise Agent Technology and Application Research Report* names the sector's pain points precisely: strict controls on minors' data privacy, algorithmic bias that can distort educational equity, and the high cost of adapting traditional classroom processes to AI. It splits the scenarios three ways — personalized teaching (building student knowledge graphs, dynamically pushing adapted learning paths), learning diagnostics (auto-generated diagnostic reports that pinpoint knowledge gaps) and campus supervision (connecting classroom audio and video data for remote lesson observation and teaching-quality trend analysis). One checkable result: after Shaanxi Railway Institute deployed its campus-supervision agent, management decision response speed rose 60%, lesson-observation preparation time fell 70%, and the teacher's teaching-optimization cycle compressed from a semester to a single class session. The report also offers a governance framework worth borrowing: during development, visual low-code orchestration, automated testing and three-tier technical, security and business review; during operations, a unified agent registry with version control, fast rollback and A/B testing; and evaluation across four dimensions — task, performance, stress and security — with hundreds of metrics and three tiers of general assessment (platform capability, generic perception-planning-memory capability, and industry-scenario fit)[10-183]. **When even a vocational college can publish checkable figures like "+60% response speed, -70% preparation time," competition in education AI stops being about concepts and starts being about governance and measurement.**

10.4.4 Failure Warnings

The collapse of LAUSD's Ed: narrative first, governance absent. [third-party verified] The Los Angeles Unified School District's AI chatbot "Ed," built at a cost of millions of dollars and billed as a "learning acceleration platform," was ultimately discontinued after vendor AllHere collapsed and its CEO departed[10-43], with an FBI investigation into contract procurement emerging along the way; the district superintendent resigned in June 2026. Technology selection and PR narrative came first, while vendor due diligence, data security, procurement compliance, and exit mechanisms were all missing — public funds and public trust were damaged together.

Chegg: commoditized by free general-purpose AI. [third-party verified] In May 2025, Chegg announced layoffs of about 22% (248 people) and closed its U.S. and Canadian offices; Q1 subscribers fell 31% year over year to 3.2 million and revenue fell 30%[10-44]. Its "homework help plus textbook rental" business model was directly commoditized by ChatGPT — the paradigmatic shock suffered by a non-AI-native organization.

2U: the bankruptcy of an asset-heavy model. [third-party verified] In July 2024, 2U, the online education operator once valued at more than US$5 billion, filed for Chapter 11 bankruptcy, with debt reduced from US$945 million to US$459 million[10-45]; court documents partly attributed the decline to "the rapid and unexpected adoption of artificial intelligence," and new OPM partnerships fell 53% in 2023–2024. The old model — high leverage, dependent on degree-program outsourcing — lacked organizational resilience.

Khanmigo's low adoption: supply is not adoption. [third-party verified] In April 2026, Sal Khan admitted that Khanmigo is "a non-event" for most students, with a deep-engagement rate of only about 15%[10-40]; a 2026 global survey by the Digital Education Council found that only 5% of students who had experienced classroom AI believed AI "changed the way they learn.[10-47]" The three-level funnel of "access → use → learning outcomes" leaks at every level — being technology-native is not the same as being organization-native.

Dushen Education: AI revenue up 664%, yet the company still loses money. [third-party] Dushen Education's (Chinese: 豆神教育) 2026 interim report shows a swing to a net loss, with AI-education revenue surging 664.32% year over year to 114 million yuan — still not enough to reverse the overall loss[10-129]. "AI revenue soaring" alongside "company-level losses" is the most typical financial shape

of the education-AI transition: transforming companies commonly offset shrinking legacy businesses with AI growth, but if the new business's gross-margin structure and scale cannot cover overall costs, the income statement stays red. Judging an education-AI company requires looking past AI revenue growth to overall profitability, customer-acquisition cost, and retention.

10.4.5 Organizational Patterns and Consulting Takeaways

Productizable teaching delivery and in-person scenarios must be managed in separate accounts. Steps that can be productized — lecturing, grading, Q&A, administration — should be AI-ized first with measured gains; in-person steps — motivation, companionship, social connection, teacher-student trust — stay with humans. GSU's success lies in embedding AI into the process; Khanmigo's lesson is in treating AI as an "inject-and-it-works" technology.

Teachers are the gatekeeper of organizational change. The resistance is not a technical problem but a problem of meaning: having teachers do "value-add / non-value-add task analysis" and see AI's value to their professional identity works better than tool training; the information gap Ithaka exposed shows that communication and incentives must precede technology deployment. China institutionalizes teacher literacy training; the EU mandates AI literacy by law — different roads, same destination: teacher capability building is the infrastructure of transformation.

"Supply is not adoption" — adoption engineering matters as much as the product. Free, platform-embedded AI still does not guarantee use; it requires teacher guidance, classroom process, and incentive structures designed as a set. Khan Academy's experimental culture proves that results come from continuous iteration, not a single deployment.

Identify the two institutional paths and design consulting approaches separately. China is policy-driven: the levers are action plans, platform scaling, and case-library diffusion, with the focus on compliant landing and regional scaling. The West is institution-driven piloting: the levers are teacher adoption, evidence of effectiveness, and governance frameworks, with the focus on single-school change design and RCT-style evidence production.

Treat evidence of effectiveness in tiers. Official claims (the Khan experiments, Squirrel AI's TIME selection) and third-party RCTs (GSU, the Khanmigo physics course) must be placed side by side and cross-checked; beware publication

bias and vendor marketing materials; and when attributing outcomes, put "pedagogical design" before "model capability" — with the same model, the embedding determines the result.

The evidence standard for education AI is moving from demonstrated effect to reproducible experiment. Eedi announced its second constrained AI-tutor randomized controlled trial, run with Google DeepMind's research team, imposing pedagogical constraints on the tutor's output to approximate the reliability and safety requirements of a real classroom[10-157]; and a peer-reviewed study in *BMC Medical Education* extends the AI-tutor discussion from general education into high-threshold medical education, emphasizing a hybrid design in which the AI digital tutor handles personalized Q&A and practice while the course knowledge structure and assessment standards provide constraint and calibration[10-158]. **Both point to the same practical principle: for an AI tutor to produce reliable results, it usually has to be tightly bound to the curriculum's knowledge structure and assessment standards, rather than used as a standalone general-purpose chatbot** — which is precisely where the constrained AI tutor research direction comes from. **AI adoption in higher education is driven first by individual students and staff, and only then forces an institutional response.** Coursera's 2026 global study found more than 95% of students and educators using AI in education; on the staff side, 90% of higher-education professionals already use AI, and institution-level adoption jumped 17 percentage points in a single year. EdTech Partners' review for university leaders frames the path as "leading AI with intention" — after broad, fast, largely self-driven individual use, institutions must add the governance layer: policy, data governance, assessment and capability building[10-181]. **This closely mirrors the corporate path of "buy the tools first, change the organization later": individual behavior always spreads faster than institutional response.**

On AI tutoring, 2026 produced the largest controlled evidence base yet. In a two-year cluster-randomized trial across 18 middle schools in Tennessee, students randomly assigned to use Khan Academy with its AI tutor Khanmigo (configured to "guide rather than give answers") did so during their existing daily math remediation block. The result: assignment raised math scores by 1.3 national percentiles per semester, equivalent to about 0.06–0.08 standard deviations per school year; with full engagement, the implied effect reaches 0.14 standard deviations. But the paper's central finding is that **the gains did not come from AI** — they were similar to Khan Academy practice without AI assistance. The reason is engagement: 96% of students

tried Khanmigo at least once, but the median student messaged the AI on only one-third of their practice days; in practice sessions with errors, only 17% asked for help, and messages were mostly direct requests for answers or clicks on suggested hints[10-214]. The researcher's summary deserves a place in every institution's acceptance criteria for AI teaching tools: **"If a motivated student wants to use it as a tutor, it is available; the problem is that most students won't use it that way."**

Between student perception and supplier enthusiasm, the gap is just as wide. Digital Education Council's 2026 global higher-education AI survey found that among students who had experienced AI in their courses, only 5% said AI "changed the way they learn," while another 28% said it "enhanced their understanding"[10-215]. **This suggests universities cannot evaluate AI by deployment rates and tool counts alone, but must track changes in student perception and learning behavior — while acknowledging that most institutions have not yet reached the depth of "changing how learning happens."**

China's path writes teacher capability into regulation. The *Guidelines for AI Application in Vocational Colleges (2026 Edition)* devotes a chapter to "improving teachers' AI teaching competence," requiring teachers not only to master methods combining AI and professional knowledge with teaching theory, but to embed industry requirements for workers' AI literacy and skills into talent-training plans, course objectives, and teaching content — with "tiered, categorized, and industry-education integrated" training for all staff, and AI education experts jointly training teachers with corporate engineers[10-216]. This pushes the teacher's role from lecturing on equipment and processes toward **designing human-machine collaborative work tasks — public-sector AI transformation depends on institutional design rather than tool distribution, with evaluation and coordination mechanisms as prerequisites.**

On the education-company side, AI-nativeness has entered the financial realization phase, and the price is real. Duolingo's core engine, Birdbrain, is a personalization model that has run for over a decade; on 30 April 2025 it generated 148 new language courses in a single day, doubling the catalog. Full-year 2025 revenue reached $1.038 billion (+39% year on year), with 52.7 million DAU (+30%) and a 29.5% adjusted EBITDA margin[10-217]. But after the leak of an internal "AI-first" memo sparked controversy, Q2 growth fell from 60% to 40%, and the stock dropped from a May 2025 high of $544.93 to about $95 in March 2026[10-217]. **AI-nativeness**

can scale cost reduction and efficiency, but the organizational communication cost and capital-market volatility of aggressive transformation are also line items in the transformation ledger. Chinese universities' AI adoption has entered an "organized, replicable" stage, while external compliance pressure is turning university governance from a voluntary best practice into a mandatory issue. The Ministry of Education's first batch of "AI + higher education" application-scenario cases covers many universities: Communication University of China's AIGC running through the whole creative process, Harbin Institute of Technology's progression from a remote lab platform to an intelligent teaching assistant to a virtual digital-human teacher, the Open University of China using iFlytek's large model to serve more than 3 million English learners a year, Zhejiang University's education-specific model "Zhihai-Sanle," and Huazhong University of Science and Technology's intelligent academic-warning and collaborative-assistance mechanism[10-249]. Abroad, compliance is a separate driving line: the EU AI Act's full compliance deadline for high-risk AI systems is August 2, 2026 (covering admissions, automated proctoring, and student-performance tracking), 31 US states introduced 134 AI-related education bills in 2026, and a UNESCO survey found 19% of institutions already have a formal AI policy with 42% drafting one[10-250]. **The due-process question of governance follows**: the American Association of University Professors argues that faculty and staff must have a voice before ed-tech is deployed and in how technology is used, proposing a standing or ad-hoc "educational-technology oversight committee" elected by each constituency — citing AAUP's 1966 *Statement on Government of Colleges and Universities* that "determining the appropriate curriculum and the procedures of student instruction is primarily the responsibility of the faculty," a responsibility that covers AI and other ed-tech infrastructure[10-251]. **The supply-side sample is equally clear**: Miami Dade College's applied-AI associate degree drew more than 750 students in its first year, and by fall 2025 more than 2,000 students were taking AI courses, with community colleges forming a National Applied AI Consortium (NAAIC) to replicate it; its key organizational move was first to form a "Business and Industry Leadership Team" of AI practitioners and hiring managers to identify local hiring demand, then to invest in faculty expansion — "scaling is easy; the hard part is keeping curricula current with the technology"[10-252].

Change on the university side comes with checkable numbers. Chinese universities' AI projects grew from fewer than 30 in 2020 to 947 in 2025, and the governance question shifted from "should we do this" to "how do we do it compliantly" — scattered projects need unified data, compute and compliance frameworks, and the university-level AI office or committee is usually only truly empowered at this stage[10-291]. On the academic side, some have tried to move "AI-native" from the corporate context into the university one: a conceptual framework and maturity model argues that AI is not a separate technology or isolated application but a "core institutional capability" embedded in teaching, administration and governance, and that a university-level maturity model must additionally handle the tension between academic autonomy and central coordination[10-292]; an external factual baseline is available in Stanford HAI's 2026 AI Index education chapter[10-293]. Meanwhile edtech funding and scale are contracting: Coursera launched a third round of layoffs during its integration with Udemy, with expected severance costs of $8-11 million — "every company is telling an AI growth story, but the first chapter of that story is usually layoffs"[10-294]; and internal commentary already notes that as AI enters administrative workflows, the value benchmark for administrative posts is being redefined[10-295]. **For universities, the lag between scaling up and governing well is the main source of risk at this stage.**

The obstacle to curriculum reform is rarely "we don't know how to use AI" — it is "we don't think anything needs to change." The Digital Education Council's *AI in Higher Education Global Survey 2026* records a mismatch: students see a relevance gap between their courses and future work, while teachers are markedly less worried that content is outdated — globally, 43% of teachers are not concerned that what they teach will be obsolete by the time students graduate. Regional variation is wide: Asia-Pacific teachers feel the greatest pressure to adapt, with 43% saying what they teach may already be outdated by graduation[10-314]. **Two 43%s pointing to opposite conclusions is itself management information: the same figure means "not worried" globally and "worried" in Asia-Pacific, so change pressure is unevenly distributed and institutions setting their reform pace to a "global average" will misjudge their own position.** The practical implication is that when administrators use student-experience data to drive reform, the first obstacle is usually not technical capability but teachers' judgment about the shelf life of their own knowledge — training answers "can they," while evaluation and incentives answer "will they."

10.5 Retail & Consumer Goods

10.5.1 Industry Profile and Bottleneck Triage

In 2021, IKEA (the Ingka Group) launched a customer service chatbot named Billie. Over three years it handled 3.2 million interactions, resolved about 47% of inquiries, and saved roughly €13 million in customer service costs[10-49] [third-party verified]. So far, this is an ordinary "AI cost-cutting" story. But IKEA did two unusual things. First, it did not lay off the roughly 8,500 customer service staff displaced by AI. Second, it carefully analyzed the remaining 53% of inquiries Billie could not resolve and found that what customers actually wanted to ask was "will this sofa fit in my home" — interior design consultation, a genuine need that had been long overlooked. The 8,500 customer service staff were retrained as remote interior design consultants and generated €1.3 billion in revenue in their first full year [third-party verified].

This story almost defines the right posture for retail AI transformation. Retail is an industry with "dual information and physical bottlenecks," at a ratio of about 60:40 — half information business (demand forecasting, assortment, marketing, membership operations), half physical business (stores, shelves, warehouses, cold chains, a million-plus employees). Bain's data shows that leading retailers using AI for personalized marketing saw ROAS improve 10%–25% in early trials[10-59] [third-party verified]; but the physical-side constraints are just as real — when Amazon closed Amazon Go, it admitted that logistics and technology excellence alone were "far from enough; you also need merchandising and display skills."[10-52]

The industry has three core contradictions. The online information flow and the offline store's physicality have long run as two separate systems: what consumers see online and what the store carries are two different worlds — and offline fulfillment remains the decisive factor for both cost and experience. Supply-chain efficiency and experience pull against each other: SHEIN compressed the industry's average inventory rate of about 30% down to single digits[10-55], while McDonald's AI ordering stumbled because "efficiency was not saved, and the experience collapsed first." Algorithmic site selection and organizational inertia are fighting for power: more than 70% of Luckin's new store locations are recommended by algorithms, yet most chain enterprises still expand on the strength of their development teams' "experience plus relationships" — the handover of power between algorithm and organization is the

hardest bone in retail AI transformation. The China Chain Store & Franchise Association's consensus is that "organizational change is the biggest challenge for AI landing"[10-60] [third-party verified].

10.5.2 Transformation Paths and Typical Practices

Retail AI transformation can be split into at least four paths.

The international giants take the "human-machine collaboration" route. Walmart deployed AI tools (real-time translation, task management) for about 1.5 million store employees in the United States and rewrote 850 million product-catalog entries with generative AI[10-57] — building AI as a "productivity exoskeleton" for frontline staff rather than a reason for layoffs [official claims]. Carrefour was the earliest to embed generative AI across the full chain: its Hopla shopping assistant covers all online channels, and more than 2,000 products use AI-generated copy [official claims]. Starbucks represents the "AI-augmented organization": Deep Brew works quietly in the back office — scheduling, stocking, predictive maintenance — freeing people for interpersonal service [third-party verified]. Amazon pushes AI into the physical layer of fulfillment: more than 1 million robots are dispatched by generative AI [third-party verified].

The essence of supply-chain AI is "trading data for certainty." SHEIN's "small orders, fast response" model pushed its inventory rate down to single digits, with 2025 revenue of US$41.8 billion and nearly 600 supplier training sessions covering 37,000 person-times[10-55] [third-party verified]; Inditex plans to invest €1.8 billion in technology and logistics, and AI demand forecasting already drives 85% of initial production-allocation decisions[10-56] [third-party verified]; UNIQLO's "Ariake Project" (Chinese: 有明计划) has invested about ¥100 billion in RFID item-level tracking, with AI forecasts wired directly to factories [third-party verified].

Chinese chain enterprises take the route of "changing the organization first, then rebuilding efficiency." In April 2026, Hema (Chinese: 盒马) merged 19 regions into 9 major regions and set up an AI committee with AI BP roles[10-51] [third-party verified]; Sam's Club, by contrast, split its regions in the opposite direction — organizational structure must match the business stage, and the directions can legitimately be opposite [third-party verified]. After DCP Capital took control, RT-Mart (Chinese: 大润发) "returned to the essence of retail" and turned profitable in FY2025 (net profit of 386 million yuan, versus a loss of 1.668 billion yuan the prior year) [third-party verified].

Consumer brands put AI to work on the business model itself. Mixue's (Chinese: 蜜雪冰城) "Snow King AI Brain" (Chinese: 雪王 AI 大脑) turns AI into a cost-control system for its value-pricing strategy — with a gross margin of only about 35%, technology is not for show but a survival necessity [third-party verified]; Pop Mart's self-developed AI integration platform, HeyLisa, uses AI sales forecasting to convert "hit-product uncertainty" into a predictable supply chain [third-party verified]; 7-Eleven Japan is the template of "data first, intelligence second" — decades of item-level management have built the data assets that make AI demand forecasting possible [third-party verified]. Deloitte's survey of 200 retail and consumer-goods executives quantifies the maturity picture for 2026, and the conclusion is "high conviction, low execution": 75% rank AI as their top strategic priority, yet only 16.5% can quantify the return; outside IT departments, broad adoption never exceeds 36%; and enterprise-wide deployment sits at just 7-10%. On governance, retail is converging on centralized AI governance (43%) while CPG has no consensus; the bigger risk is not which model is chosen but that 54% of AI strategy ownership sits with technology leaders rather than the P&L owners who must deliver outcomes. Value structures also differ: CPG leads in product development (27% versus retail's 18%), while retail leads in revenue growth (38% versus CPG's 10%) — retail's investment is converting into commercial results, while CPG remains at the operational layer[10-184]. **"Who owns the strategy" predicts success better than "did you buy AI."**

In restaurants, the AI ledger starts on the cost side. The backdrop: China's restaurant market has passed 5.79 trillion yuan in scale, yet average profit margin is only 4.8% and industry survival stands at 77.6% according to the China Cuisine Association; the Action Plan for Promoting Intelligent Layout in the Catering Industry (2026-2028) calls for full-chain intelligence penetration above 70% among group-dining, fast-food and tea-and-coffee chains by the end of 2028. Restaurants that have deployed intelligent supply-chain systems cut ingredient waste from 8-12% to 3-5% and inventory waste by 53%, while AI demand forecasting issues purchasing recommendations two days ahead and compresses ingredient turnover to two days. Commercial cooking robots have fallen from over 100,000 yuan three years ago to a mainstream 3,000-5,000 yuan band, shortening payback from two years to 8-12 months, and coverage is expanding fast (Laoxiangji in more than 380 restaurants, Xiaocaiyuan in nearly 200). Another judgment worth recording concerns data sovereignty: merchants using platform point-of-sale systems keep their membership data inside the platform ecosystem, and "once you want to switch systems, migration

costs are extremely high, and some historical data cannot even be exported" — which is why a substantial share of the 18 deals and roughly 2.8 billion yuan raised in restaurant AI in 2025 went to solutions supporting private deployment and data self-control[10-186]. **When average industry margin is 4.8%, the first AI report card is always a cost statement — and data ownership determines who ultimately keeps that statement.**

AI in apparel has reached second-level steps. Yien's report offers concrete data points: AI quality inspection in a Dongguan Humen plant automatically identifies fabric defects at about 95% accuracy; AI design compresses the time to generate a new design rendering from two days to three seconds; and Zhijing Technology's "fabric-seeking robot" cuts fabric search from hours to three minutes. On the demand side, "AI styling" interest skews toward Gen Z women in tier-one and new tier-one cities pursuing efficiency and creative expression, focused on style matching, the realism of virtual try-on and ease of use — while negative reviews about implausible aesthetics and distorted results persist[10-187]. **AI can now produce a proposal in seconds, but consumers' bar for "does it look right, is it accurate" has not come down — the speed dividend has to be cashed through a quality gate.**

10.5.3 Benchmark Cases

IKEA's Billie: the unsolved problems AI reveals are worth more than the ones it solves. [third-party verified] Back to the opening story. IKEA's pivotal move: it did not cut the customer service staff displaced by AI; instead, it followed the questions AI could not answer to discover "interior design consulting" — an overlooked market — and retrained 8,500 customer service staff as remote interior design consultants, who generated €1.3 billion in revenue in their first full year (about 3.3% of group revenue)[10-49] [third-party verified]. This is the most important positive sample of AI-native organizational transformation: the unsolved problems AI reveals are worth more than the problems it solves, and the freed-up workforce is redeployed into higher-value work — organizational transformation is a technology decision and a talent decision happening at the same time.

Luckin: algorithmic site selection and the "Smart Brew Ecosystem." [official presentation; data not independently verified] As of May 31, 2026, Luckin had more than 35,000 stores worldwide and 473 million cumulative transaction customers. Three hard metrics stand out: more than 70% of new store locations are recommended by algorithms, and the average cycle from application to acceptance is

18 days; IoT-connected devices exceed 700,000 with a 99% online rate; and intelligent ordering has doubled efficiency. Its self-developed agent, AI Lucky, has been integrated into super-apps such as Qwen (Chinese: 千问), WeChat, and Alipay, and supports voice ordering. Luckin has also joined with multiple cloud vendors to build the "Smart Brew Ecosystem"[10-50] (Chinese: 智萃生态圈), upgrading AI from point tools to platform capability.

Hema: the governance pairing of an AI committee with a region-based structure. [third-party verified] In April 2026, Hema completed its organizational upgrade from a city-based to a region-based structure, consolidating 19 regions into 9; it simultaneously set up an AI committee led by the CTO and created AI BP roles[10-51], connecting AI capability directly with business needs. The backdrop: nine consecutive months of overall profitability in 2024 and the first full-year positive adjusted EBITA in FY2025 (per EO Intelligence's review). "Committee + BP roles" is a common mechanism for linking the technology center with business units — moving governance structure and organizational structure in sync is the biggest difference between Hema and the many retailers that "only install tools without moving the organization."

Bosideng: AI enters design; people transform first. [third-party verified] Bosideng (Chinese: 波司登) has embedded AI into the front end of "trend insight → design generation → rapid sampling": in 2024, eight AI-generated patterns and nine AI-designed garments reached the market, and the first product fully landed through AI design — a single-shell jacket — was well received[10-130]. The deeper organizational work sits in the supply chain: since 2018 its "one pool of global goods" (Chinese: 全球一盘货) consolidated more than 100 warehouses nationwide into a single central warehouse, using a "merchandise bank" mechanism that removes ownership tags and replenishes dynamically by sales; after the SAP EWM upgrade, real-time inventory updates and complex analytics ran 1,000x faster, inventory turnover fell from 175 days (FY2020/21) to 115 days (FY2023/24), warehouse automation exceeds 90%, and the plan is for a 10,000-square-meter warehouse to need only one person[10-131]. Its logistics director's judgment is worth remembering: technology can be bought and outsourced, but brand philosophy and mindsets cannot — transformation starts with changing people, not with going live on systems.

10.5.4 Failure Warnings

Amazon Go/Fresh closures: being technologically ahead is not the same as having a working business model. [third-party verified] In January 2026, Amazon announced the closure of all 58 Fresh supermarkets and 14 Go stores, accompanied by 16,000 layoffs[10-52], admitting it had "not yet created a sufficiently distinctive customer experience and the right economic model." Go's Just Walk Out "grab-and-go" technology was dazzling, but it could not hide mediocre merchandise; tellingly, Just Walk Out succeeded when sold as a technology to 360+ third-party locations. Retail AI must solve both "differentiated experience and unit economics" at once — technology inside the wrong business model is merely expensive decoration.

McDonald's × IBM voice ordering: the triple threshold of accuracy, cost, and experience. [third-party verified] In June 2024, McDonald's terminated the AI voice-ordering system it had been testing with IBM since 2021 across 100+ stores. Analysts pointed out that accuracy reached only 80–85%, below the 95% threshold[10-53], and operating costs were higher than human labor — and the viral TikTok video of "AI getting a McNuggets order wrong" amplified the experience collapse. Retail AI must clear the triple threshold of "accuracy, cost, and experience"; the gap between a technology demo and a real operating environment is far larger than imagined.

Yonghui learning from Pang Dong Lai: easy to copy the form, hard to copy the spirit. [third-party verified] After more than two years of remodeling, Yonghui's (Chinese: 永辉) remodeled stores saw average single-store foot traffic grow over 80%, yet the company still posted a 2025 net loss attributable to shareholders of 2.55 billion yuan, with cumulative losses from 2021 to 2025 approaching 12.05 billion yuan[10-54]. The comparison is stark: Pang Dong Lai (Chinese: 胖东来) employees earn an average monthly salary above 9,500 yuan with a turnover rate of only 0.33%, while Yonghui's remodeled-store staff earn just 4,500–6,000 yuan a month — 65% of Pang Dong Lai's pay for the same roles — with no profit-sharing mechanism in place. Pang Dong Lai's essence is a distinctive ordering of scale, profit, and employee relations, and its regional supply-chain density cannot be replicated by national chains. The contrast between "whole-company statements and store-level results" is fire and ice — one of the most profound lessons in organizational transformation. **Adoption is not the bottleneck; frontline absorption is.** The *State of AI Readiness in Retail 2026* places independent measurements from different tools side by side and states

the caveat plainly: these are not a single measurement[10-185]. One end is IBM IBV's survey of 1,500 executives — 96% of retail and consumer-goods executive teams use AI (81% of the executives themselves); the other is UKG's survey of 8,200 frontline workers in ten countries — only 33% of retail, hospitality and foodservice frontline staff use AI at work, five points below the 38% cross-industry frontline average and second lowest of the seven industries measured; and in Accenture's 19th holiday shopping survey, only 5% of U.S. retailers expected to be fully optimized for generative-AI-driven customer engagement by 2026. As context, the report cites generative AI value of $240-390 billion for retail, equal to 1.2-1.9 points of industry margin. **The diagnostic metric for retail AI should move one level down from "executive adoption": whether the frontline is on board is the real sign that transformation has begun.**

10.5.5 Organizational Patterns and Consulting Takeaways

The AI-native transformation of retail is, at bottom, the re-orchestration of two systems: the "information flow" and the "physical flow." Online-offline integration is not about moving products onto the internet; it is about letting demand signals (online searches, membership data) and supply actions (store restocking, production scheduling) share the same data foundation. A consultant's first move should be to take stock of whether item-level data assets exist and whether they are connected — 7-Eleven proves that AI's moat is not the model but the data-organization discipline of "item-level management."

Supply-chain data foundations set the ceiling for AI. SHEIN's small-order fast response, Inditex's 85% of production allocation decided by AI, and UNIQLO's RFID full chain all point to the same thing: the effectiveness of supply-chain AI depends on how deeply the industry chain is digitalized, not on model parameter counts. Retail AI is an "asset-heavy" transformation — you trade data infrastructure for certainty in inventory and cash flow.

Store employees' roles must be rebuilt, not eliminated. IKEA retrained 8,500 customer service staff, Walmart handed AI tools to 1.5 million employees, and 7-Eleven Japan uses AI avatars to cope with labor shortages — all point toward a "human-machine hybrid" organizational form. Layoff-style AI transformation in retail directly destroys the physical-side asset of store experience.

Consumer trust is the hidden ceiling of retail AI. Walmart reports that consumer trust in AI recommendations (27%) has already overtaken influencer-driven shopping (24%)[10-58], but gaps in privacy protection can void the promises of transformation [official claims].

Organizational structure must match the business stage and digital maturity. Hema merging regions (an expansion phase seeking scale) and Sam's Club splitting regions (a high-growth phase seeking flexibility) moved in opposite directions and both worked; Yonghui's "easy to copy the form, hard to copy the spirit" shows that copying a benchmark's surface practices without simultaneously adjusting interest-distribution mechanisms leaves transformation stranded in isolated corners of the financial statements. The landing point of retail AI consulting is never model selection; it is the simultaneous re-arrangement of the data foundation, the organizational structure, and the interest mechanisms.

Ownership of the dialogue layer is becoming the new battleground. U.S. retailers Kroger and Lowe's, together with Papa Johns and others, are testing their own AI-agent stacks rather than depending on a single third-party chatbot platform — the rationale is to keep the "find product → place order → after-sales" conversational entry point and first-party data control in their own hands, while switching across multiple LLM vendors to manage cost and risk[10-132] [third-party verified]. The ownership contest over retail entry points is extending from "shelves and apps" to the "dialogue layer": whoever owns the conversation with the customer owns the next generation of shelf space.

Ownership of the conversational layer is now being discussed institutionally. An IBM Institute for Business Value report argues that brands should own the agentic-commerce experience rather than be intermediated by AI entry points[10-160]: when shopping decisions are made by consumers' own AI agents, brands lose control over discovery, comparison, and purchase, and must win back the right to be recommended through data and experience. The Chinese counterpart comes from the case collection in the *2026 China Consumer & Retail LLM Application Tracking Report* — Kids Want's AI agent service upgrade, Feihe's full-chain intelligence, Yili's content-marketing agent, and Peacebird's full-funnel marketing AI[10-159] [third-party, cited report] — which together show Chinese retail agents expanding from single-point tools into full-chain organizational capability.

Retail's failure mode differs from other industries: it is often "failure to define the objective." Industry analysis in 2026 points out that many retailers rush to deploy AI customer service or recommendation systems without clearly defining success — whether the goal is higher conversion, higher average order value, or better retention. Unclear standards mean the project cannot prove value and therefore cannot keep its funding[10-219]. This complements manufacturing's "data and integration shortfalls" and banking's "broken organizational coordination": retail's metrics (conversion, order value, retention, return rate) frequently conflict, so optimizing one can worsen another. **Without choosing a primary metric in advance, the effects of AI cancel each other out in internal evaluation — the clearest industry sample of "metric governance before technology selection."**

At the same time, differentiation in retail is returning to merchandising power. Walmart (Chinese: 沃尔玛)'s new-generation store model in Chengdu covers about 3,000 square meters, focuses on fresh food and groceries, and uses its private label Marketside as a key differentiator; Walmart China's CEO summed up the shift as "a return to customer-centricity"[10-218]. **Once algorithms and data become industry-wide commodities, what to sell and to whom becomes the dividing line again — agents rebuild the efficiency structure of decisions and execution, but merchandising judgment and commercial taste still have to be carried by people.** That is where this book's "post-AI amulet" discussion lands in retail. **Discussion of retail AI transformation is shifting from "front-end experience" to "back-end organizational cost," and the magnitude is striking.** BCG's judgment: retail's three strategic capability stacks (merchandising, customer growth and digital activation, and technology) will account for about 70% of the above-store employee cost of "destination retailers," and under the new capability mix, above-store organizational cost can fall to a tenth of its former level; the key change is that models and algorithms are "no longer the bottleneck to scaling AI" — what is really needed is the largest workforce transformation since the personal computer, plus years of investment in reskilling, real-time data, human-machine workflows, and platform modernization[10-253]. **Value is often realized by "connecting one correct external signal to one specific business decision," not by the technology itself**: Unilever connected weather forecasts to an AI agent for ice cream demand sensing and reported about 30% sales growth in key markets where the model was deployed; PepsiCo concentrates its analytics investment on

"four to five high-conviction use cases" at any one time rather than spreading capability thin[10-254]. NRF 2026 bet its theme on "agentic commerce": Google announced a new protocol, enterprises brought AI in from customer experience to operations, and luxury brands stressed that "humanity should take priority over technology" — LVMH pushing "AI for All," Ralph Lauren's AI shopping assistant — with the common thread of "using AI to enhance customer service rather than replace human contact"[10-255]. The domestic Chinese view gives a blunter organizational staging: retail digitalization has three stages — dashboard (managing by data), assisted driving (systems advising on replenishment and scheduling), and full self-driving (fully system-decided once validated) — with AI entering fully in the second and third stages; PwC Strategy& projects that global retail annual operating profit will rise by $310 billion by 2030, and that retailers pushing AI organization-wide could lift operating margin from the industry-average 3% to 14.4%[10-256].

Failure rates need to sit in one table. RAND puts overall 2025 AI project failure at 80.3%, MIT (NANDA) says 95% of generative AI pilots fail to scale, S&P Global says 42% of enterprises abandoned AI projects in 2025 (up from 17% in 2024), and the average failed project costs $7.2 million[10-296]. A former global CIO puts the prescription more bluntly: against both failure rates, "bigger budgets and more people will not solve this" — the deciding factors are conditions such as culture, judgment and trust, summed up in a quotable line: "culture is not soft — it is the infrastructure the entire organization runs on"[10-297]. **Retail AI projects stall at the pilot stage mostly not because the model is not good enough, but because nobody first answered who owns things after the pilot ends.**

10.6 Government & Public Services

10.6.1 Industry Profile and Bottleneck Triage

In February 2025, 70 "digital-intelligence workers" (Chinese: 数智员工) began their jobs in Futian District, Shenzhen. Built as AI digital humans that fuse DeepSeek with local knowledge bases, they cover 11 major scenario categories across 240 government scenario terminals: document-formatting correction accuracy exceeds 95%, review time is cut by 90%, routing accuracy for public livelihood requests improved from 70% to 95%, and personalized custom generation was compressed

from 5 days to minutes[10-62] [official claims + third-party verified]. This is the landmark implementation of the "AI civil servant" concept, and it pushed government AI from demonstration toward daily operations.

Government and public services is one of the few industries where the "information and physical bottlenecks" are split roughly fifty-fifty: approval processing, policy consultation, document drafting, and service-request routing are information-intensive links, while counter services, on-site law enforcement, grid patrols, and urban infrastructure operations remain firmly bound to the physical world — in sharp contrast to finance's 80:20 information-dominant structure. This determines that government AI transformation must be a dual-track overhaul of "online intelligence + offline coordination," rather than a purely digital reconstruction.

The core contradiction has three layers. First, the paradox of data security and sharing: government data is scattered across departments, with unclear powers and responsibilities and poor circulation — "data silos" have long been the No. 1 pain point; the state's creation of a national data administration is precisely aimed at breaking this deadlock[10-68], yet local practice generally finds "consolidation easy, coordination hard" — data-management responsibilities have not been synchronized with powers over project approval, funding, and staffing. Second, digital formalism: the deployment guidelines issued by the Cyberspace Administration of China (CAC) singled out for criticism "blindly chasing technological superiority, duplicate construction, and forced usage," and People's Daily Online likewise warns against bandwagon construction "for the sake of using AI." Third, the decision-accountability chain: once AI-generated official documents, replies, or handling recommendations go wrong, there are no mature institutions for responsibility assignment, human fallback, or algorithmic transparency. The US federal government faces a mirror-image dilemma — the Brookings Institution found its AI use cases highly concentrated in a few large agencies, with uneven diffusion, and procurement and budget mechanisms constituting structural barriers[10-70] [third-party verified].

10.6.2 Transformation Paths and Typical Practices

Chinese government AI transformation shows a clear "policy-chain-driven" character: "AI+" was written into the Government Work Report in 2024; in August 2025 the State Council issued the *Opinions on Deepening the Implementation of the*

"*AI+*" *Action*; and in October of the same year the CAC released the *Guidelines for the Deployment and Application of AI Large Models in the Government Sector*[10-61] — completing the chain of "top-level design — special action — scenario guidelines."

The core of the deployment route is "centralized, consolidated planning": the guidelines specify that counties and below should in principle reuse higher-level compute and model resources rather than independently building government LLMs, exploring "build in one place, reuse across many regions and departments" to prevent "model silos[10-61]." At the same time, they delineate four major scenarios — government services, social governance, agency office work, and decision support — and emphasize the LLM's "assistive" positioning and the discipline that "classified information never goes online." DeepSeek's open-sourcing, with its low cost, high performance, and easy deployment, dramatically lowered the threshold for adoption, and domestic adaptation (Ascend chips, all-in-one appliances) became the standard.

At the organizational level, the National Data Administration (Chinese: 国家数据局, established in October 2023) has become the "organizational hub" of digital transformation: 2024 was positioned as the "year of institution building," shifting to the "year of reform breakthroughs" in 2025, with 23 provincial-level data administrations formed by the end of 2024. In terms of implementation forms, the "City Brain" has been elevated from a technology platform to a city-level governance mechanism reconstruction — Chongqing, relying on its integrated intelligent public data platform, automatically generated response plans such as police deployment and subway flow control through 5G + AI video analytics when daily footfall in the Jiefangbei business district exceeded 1.8 million[10-71] [third-party verified]. On the grassroots governance side, Chongqing's "141" system embeds AI across 1,031 townships and streets and 62,000 grids; the 12345 hotline has become the densest entry point for agents, with Guangzhou, Suzhou, and Jinan all deploying full chains of "smart form-filling — knowledge recommendation — smart dispatch."

The top-level framework continued to thicken in 2026. *Research Report on Government Agent Development (2026)*, released at WAIC 2026 by Peking University's School of Government in collaboration with CAICT and others, traces how the full agent architecture of perception–planning–execution–memory is extending into government. It finds China has already formed a multi-domain, multi-level pattern in which high-frequency service use cases accelerate, operational-coordination cases advance steadily, governance-and-analysis cases remain exploratory, and discretionary-decision cases proceed cautiously, and it identifies three build models:

unified-foundation, business-driven, and knowledge-enabled. The report builds a three-dimensional evaluation framework of lifecycle stage × agent core component × quality-evaluation set, and compiles 30 representative practices. Its core judgment: **the focus is shifting from whether AI can be applied to which scenarios fit, how far to apply it, how to evaluate results, and how to keep risk under control**[10-162] [third-party, institutional report]. The national governance framework for agents filled a key gap in 2026: the Cyberspace Administration of China's Implementation Opinions on the Regulated Application and Innovative Development of Agents defines an agent as "an intelligent system with autonomous perception, memory, decision-making, interaction and execution capabilities" and puts security and controllability first[10-188]. At the local level, Beijing's Action Plan for Deepening the "One-Net-Through" Reform and Advancing Digital-Intelligent Government Services (2026-2027) opens with full-process service intelligence, and its most easily overlooked — yet most decisive — prerequisite is knowledge governance: building a government-service knowledge hub and a city-wide unified knowledge base, issuing knowledge-governance standards, establishing knowledge operations and management mechanisms with routine collection, processing, labeling and updating, and only then integrating unified consultation and referral services across channels such as Jingtong[10-189]. **The ceiling on AI quality is set by how well the organization's knowledge is organized — in hospitals it appears as "document quality becomes AI discipline," and in government as "knowledge operations written into the action plan."**

10.6.3 Benchmark Cases

Shenzhen Futian: 70 AI "Digital Workers" [official claims + third-party verified]

The first batch of 70 digital workers is built on DeepSeek fused with local knowledge bases, covering 11 major scenario categories and 240 government scenario terminals[10-63], forming a closed loop of "demand — training — scenario application — iteration," supported by a unified management platform that handles full-lifecycle management of these digital workers. Its significance lies not in the technology but in turning the "AI civil servant" from a concept into an operable, day-to-day reality.

Shenzhen's "Shen Xiao-i" (Chinese: 深小i): A Public-Facing Government Agent [official claims]

Launched on February 22, 2025, it is the country's first practical AI government assistant open to the public, embedded in the full "ask, search, guide, process, review" service flow. It has cumulatively handled over 4 million intelligent Q&A sessions, with a response rate above 97% and first-answer accuracy above 94%, and is one of the first 7 government agents to pass evaluation by CAICT's TEL Laboratory (Chinese: 信通院泰尔实验室). Behind it is Shenzhen's AI platform: managing 270P of compute, 39 deployed models, and 97.38 million annual calls[10-64], with 10 scenario challenges organized through open-competition recruitment (Chinese: 揭榜挂帅) — platform-based supply plus scenario-based open challenges brings it closer to "AI-native" than single-point applications.

Guangzhou: China's First Domestically Adapted Government DeepSeek [official / third-party verified]

Adaptation was completed and rolled out broadly in January 2025: the 12345 hotline answers 50,000 calls daily, and the intelligent agent-seat system has cut caller waiting time by 43% and achieved 97% accuracy in work-order routing[10-65]; the Digital Guangzhou Innovation Laboratory has adapted over 150 LLMs and opened the country's first government-grade compute center running the Ascend-adapted DeepSeek-R1 671B; the Guangzhou Intermediate People's Court deployed the country's first private government DeepSeek all-in-one appliance; Yuexiu District's "Ai Xiaoyue" (Chinese: 艾小越) achieves 99% answer accuracy. Guangzhou has proposed "one ledger, one mechanism, one platform" for LLMs, building a two-way loop in which "data feeds AI, and AI feeds decisions back."

10.6.4 Failure Warnings

AI Hallucination: Errors in Government Are Irreversible [third-party verified]

Outlook Weekly (Chinese: 瞭望) dissects three causes of hallucination: insufficient or biased training data, algorithmic architecture limitations, and the probabilistic nature of generation[10-67]. LLMs "confidently spouting nonsense" can cause erroneous decisions and damage to public trust in highly regulated domains such as government and the judiciary — once a mistaken policy interpretation reaches the public, it constitutes real harm. CAICT experts point out that hallucination governance requires both "technology and institutions": retrieval augmentation and fact-checking on the

technical side, and content review, risk warnings, and accountability tracing on the institutional side. This is precisely why the CAC guidelines require prominent risk warnings in the interface.

The GAO Audit: Governance Lagging Behind Deployment [third-party verified]

In its July 2025 review of 12 federal agencies, the US Government Accountability Office (GAO) found incomplete governance frameworks, use-case inventories not updated in time, and inadequate risk management for generative-AI-specific issues such as hallucination, data leakage, and copyright[10-66]. US federal AI use cases grew fivefold in five years to 3,611, yet governance cannot keep pace with the speed of diffusion. The GAO's framework of "use-case inventory + risk classification + accountability auditing" suggests: build governance first, then talk about scale.

Digital Formalism: Advanced Technology, Lagging Experience [third-party verified]

The CAC guidelines explicitly require guarding against digital formalism; People's Daily Online criticizes bandwagon construction "for the sake of using AI"[10-69]; the magazine *Qunzhong (Mass)* (Chinese: 群众) warns of "advanced technology, lagging experience." The more hidden failure is organizational: mismatched powers and responsibilities of local data administrations leave coordination spinning in place. Government AI usually fails not because the models are inadequate, but because governance and organization have not kept up.

A stampede to deploy DeepSeek carries four risks. [third-party / think-tank analysis] People Zhongke Research Institute (Chinese: 人民中科研究院) argues that simply deploying DeepSeek or similar large models without systematic planning exposes local governments to four risks: resource waste and efficiency imbalance (duplicated construction without unified planning), data-security and compliance hazards, unguaranteed content accuracy, and application–business disconnect producing "AI for AI's sake"[10-133]. Government large-model deployment should shift from a "model procurement race" to integrated construction across scenarios, data, and institutions — build the governance framework before launching applications; performance-driven rush deployment risks creating a new form of digital formalism.

10.6.5 Organizational Patterns and Consulting Takeaways

Institutions first determine the order of deployment. The rollout sequence of government AI is set by policy and security boundaries rather than technical difficulty: the CAC guidelines are both a constraint and a roadmap, and its three principles — scenario classification, centralized consolidated planning, and the assistive role — should be the preconditions for initiating any government AI project.

The assistive role is both politically correct and engineering-correct. The stable form of government AI is the "digital colleague" rather than the "digital replacement": repetitive, standardized work goes to AI, while value judgments, emotional communication, and discretionary authority stay with people, with "human fallback" as the final line of defense against hallucination risk.

The data administration is the real lever of organizational change. Government AI transformation is essentially a "data-administration-driven organizational rearrangement": the restructuring of tiao-kuai (vertical-line and horizontal-block) relations across national, provincial, and city/county levels, paired with organizational instruments such as leading groups, standardization technical committees, big-data professional-title review, and zero-based budgeting, determines success or failure more than any single technology procurement.

Grassroots burden reduction must be measured. Shenzhen Nanshan's AI identified 87,000 public requests, improved key-information accuracy by 30%, and captured 820 weak risk signals — burden reduction backed by data is the only real "burden reduction," while forced usage and duplicate form-filling are a new form of formalism. The first consulting move should be helping clients build the governance foundation of "use-case inventory + risk classification + accountability auditing" (modeled on the GAO framework and CAICT's case-evaluation mechanism), and unifying value metrics such as "number of scenarios, hours saved, accuracy" — otherwise government AI will repeat the failure of "statistical prosperity, frontline indifference."

The "small but deep" in-house product route: Singapore's Pair suite. [third-party / international-organization case] UNDP's review of Singapore's government AI tool suite Pair describes an approach that inverts the big-bidder playbook: developed since mid-2023 by the internal experimental team OGP rather than outsourced to a large systems integrator, with all data retained inside government and never logged by cloud vendors, and each product defining its

evaluation criteria before any new model goes live. Pair now has 60,000+ registered users and 20,000+ weekly actives, has exchanged over 10 million messages, and is estimated to save civil servants about 46% of administrative time — Pair Noms compresses meeting minutes that once took hours to a full day into under an hour[10-134]. Compared with "big and complete" government-model platforms, "small but deep" in-house products let AI penetrate civil servants' daily work in the form of an office tool before extending into government scenarios — the adoption path and procurement logic, more than the model itself, decide success.

AI written into a strategy does not automatically become real impact. The ITIF Center for Data Innovation's *Public Sector AI Adoption Index 2026*, based on a survey of 3,335 public servants across the United States, the UK, Germany, France, Japan, Brazil, South Africa, India, Singapore, and Saudi Arabia, shifts the measure from adoption rates to the institutional conditions that let AI be used effectively and responsibly — enthusiasm, empowerment, enablement (clarity of available tools and leadership guidance), embedding in daily work, and access to training. In countries with clear guidance and support, 91% of public servants were confident about using AI, 82% were optimistic, and 79% felt empowered by it[10-161] [third-party, survey index]. **The next step for government AI is not buying more models but completing the organizational chain of guidance, tools, training, and embedding. A government LLM and a government agent are not the same thing.** Pang Rui of East China Normal University offers a useful distinction: the government LLM is the cognitive hub, solving "understanding and thinking," and its typical applications remain static instruction-response loops (Q&A, drafting assistance) — in essence a passively invoked administrative knowledge brain. The government agent adds the capacity to act, autonomously completing task flows around a governance objective by fusing perception, memory, planning and action into a closed loop of intent recognition → process orchestration → analytical decision → tool invocation → execution feedback → validation and optimization. In short: from thinker to actor, from knowledge assistant to governance partner. Two boundary conditions belong in any government AI proposal: technical efficiency cannot substitute for governance safety — effective intelligent governance requires data resources, organizational mechanisms and human capability together, or it slides into "technical idling" — and AI may assist decisions but cannot replace public-value judgment;

agents must operate within institutional rules and accountability boundaries, with a regulatory sandbox for new risks such as algorithmic bias, goal displacement, hallucination and prompt injection[10-190].

"Process debt" could become the second form of digital formalism. Among IDC FutureScape's ten predictions for Chinese smart-city governance, the most directly relevant are: by 2027, 70% of cities will deploy AI agents across systems and data to orchestrate end-to-end workflows while managing misuse, overreach and "process debt"; by 2027, 70% of provincial and municipal governments will invest in fine-tuning LLMs on data they had never touched, mining value from decades of protected archives and isolated systems; and by 2029, 50% of local governments will trigger and automate service flows by detecting livelihood events, moving public services from "passive application" to "event-triggered, proactive delivery." IDC notes that China takes an application-led, industry-enabled path, focusing on algorithm optimization, model compression and engineering because of compute constraints, to maximize efficiency per unit of compute. Its closing reminder deserves quoting in full: the real challenge is whether processes, organization and capabilities are rebuilt around a people-centered city — otherwise AI amplifies process debt rather than absorbing it[10-191].

Judicial standards are the second external constraint, beyond regulation. On September 7, 2026, China's Supreme People's Court issued its Opinions on the Lawful Adjudication of AI-Related Disputes (Fa Fa [2026] No. 10), establishing systematic adjudication rules for AI controversies[10-192]. Once AI enters production and service processes, questions of liability, ownership of rights and evidentiary form reach the courts in volume, so organizations face not only regulatory requirements but judicial standards — and how liability is defined in court feeds back into process design and audit-trail requirements, especially in high-risk settings such as healthcare and government where liability gaps remain. **Compliance lists expire and adjudication rules evolve — designing the audit trail into the process is far cheaper than explaining afterwards why it exists.**

The benefits and the costs of government AI were recorded side by side in 2026. Alberta, Canada reported that roughly 50 coding agents scanned 466 million lines of code in about 20 hours, compressing a benefits-portal rebuild from five months to four to five days with costs down about 95%; the same public-sector deployment index also collected negatives: privacy concerns over a facial-recognition pilot, a model labeling an anthology of Holocaust literature as "DEI-related" in a 143-

page ruling that found unconstitutional viewpoint discrimination, and an immigration-enforcement agency barring smart glasses over data risk[10-220]. **The same technology can deliver two orders of magnitude in time and cost savings, and can also cause discrimination, privacy, and compliance incidents where review was insufficient — the difference lies in whether scenario screening, authorization scope, and human review were designed in before deployment.**

The gap between "already scaled" and "has rules" was quantified for the first time. Granicus's *2026 Digital Government Trends Report* found 55.7% of government agencies already use AI, but only 42.9% have a formal AI policy; adoption relies mainly on off-the-shelf platforms (ChatGPT 64.8%, Microsoft Copilot 61.1%, with very few building their own models); and value concentrates in productivity scenarios — 100% of AI-using agencies use it for research tasks, 60% for workflow orchestration, and 60% for departmental reports and summarizing public comments[10-221]. **Governance lag and budget constraints form the pair of practical bottlenecks for deepening government AI: adoption expands faster than legislation and institutions update.**

On the regulatory side, frameworks are being filled in quickly. China's Cyberspace Administration issued the *Implementation Opinions on the Regulated Application and Innovative Development of Agents*, defining an agent as an intelligent system with autonomous perception, memory, decision-making, interaction, and execution capabilities, and stating that "security and controllability" must be upheld with agent security given priority — the country's first systemic policy document focused on agents, and the common rule base cited by government, healthcare, and financial institutions[10-222]. International organizations supplied a "foundations" argument instead: the OECD's *Digital Government Outlook 2026* finds AI use inside government expanding markedly but highly uneven across policy domains — fast where data is available and processes standardized, slow where legacy systems, skills gaps, and high transparency requirements constrain it. It stresses that adoption levels depend on the quality of the foundations (high-quality interoperable data, coherent digital public infrastructure, adaptive procurement models, and a civil service with AI skills) and warns that **"not adopting AI is itself a risk"**[10-223]. **Public-sector AI is moving into the deepest water: institutions and headcount establishment.** Shanghai's establishment-management authorities have explored a representative direction: using NLP to parse workload, historical efficiency, and internal/external

evaluations into a multi-dimensional model for institutional adjustment, simulating the effect of adding or cutting institutions and headcount on service efficiency; on establishment management, building a panoramic profile of personnel structure, activating a "revolving pool" of establishment, and piloting a "fixed establishment + AI-efficiency establishment" dual-track plus a digital "twin institution" model[10-257]. **Once AI is written into the establishment, it turns from a "tool" into an "organizational element."** Service-side results are quantified in Shenzhen's annual list: it launched "Shen Xiao i," the country's first practical public-facing AI government assistant, and its 45 "handle a matter efficiently in one go" services each cut an average of 8 steps, 11 days of processing time, 4 trips, and 12 documents; "talent-introduction household registration in one go" cut processing from an average of 7 days to under 30 hours (as fast as 24 minutes)[10-258]. The comparable international example is San Francisco's scale-up: Microsoft 365 Copilot Chat expanded from a pilot with 2,000-plus employees to nearly 30,000 employees for data analysis, project planning, and research — for public-service workers like social workers, the time saved means more direct service[10-259]. **The most transferable organizational lesson comes from Taiwan**: treating process knowledge as an organizational asset to be rescued — a no-code platform lets employees describe their methods in natural language and the system auto-generates an agent; each department appoints a "knowledge manager" to regularly feed "questions the AI couldn't answer" into the knowledge hub (the author says answers are added within about three days on average), and a "citizen developer" drive asks each employee to build five agents a month; the insight is that "traditional knowledge management only retains static industrial knowledge, while the crucial process knowledge walks out with the person and disappears when they move"[10-260]. **But speed must not outrun accountability**: Infor argues for "accountability over speed," holding that what really stalls public agencies is not the model but "operational readiness" — workflows, data, controls, guardrails, and oversight must be in place before an agent is allowed to act[10-261].

Public-sector adoption is not a procurement decision but an interdepartmental, interagency institutional journey. A US state-government assessment splits it into readiness, pilot, implementation and impact, stressing that because the technology moves fast the path is iterative rather than linear and that most states are still early[10-298]. The same assessment offers a reusable organizational finding — **states that establish an AI center of excellence, an enablement lab**

or a cross-agency committee are better able to scale operational AI; an infrastructure gap is widening between leaders who build reusable platforms and enablement centers and laggards who work in silos and manage isolated pilots. At the international-organization level, the OECD agrees: AI can support and accelerate administrative and support tasks, but realizing that potential requires systematically restructuring skills, roles and training[10-299]. **For government organizations the implication is: build the "who coordinates" institution first, then debate "which model."**

10.7 Logistics & Supply Chain

10.7.1 Industry Profile and Bottleneck Triage

On May 22, 2025, the automated terminal at Qingdao Port (Chinese: 青岛港) pushed its average per-quay-crane operating efficiency to 62.62 natural containers per hour — the 13th time it has broken its own world record for automated-terminal handling efficiency[10-73] [official claims + third-party verified]. The terminal was approved in 2013 and construction began in 2015; ten years of continuous iteration have taken it from an "unmanned terminal" to "whole-domain intelligence." It is a reminder to everyone: AI in logistics is a heavy-asset, long-cycle systems-engineering effort — not something that shows results just by installing software.

Logistics and supply chain have an information-to-physical bottleneck ratio of roughly 40:60, the mirror image of finance's 80:20. Beneath the heavy-asset surface, what actually drives the entire network is decision information — forecasting, scheduling, routing, and risk control. Data from the China Federation of Logistics & Purchasing (CFLP) (Chinese: 中物联) shows China's logistics industry generated total revenue of 13.2 trillion yuan in 2023; industry estimates put the global AI-enabled smart logistics market above US$42.8 billion in 2025, with over 1.5 million warehouse robots deployed [third-party verified].

Logistics AI transformation faces three structural contradictions. Automation is a heavy-asset investment, yet demand is highly volatile: an automated terminal costs billions of yuan and takes years to build, while demand fluctuates on a weekly basis — capital expenditure and capacity utilization are structurally mismatched. Physical-world right-of-way and compliance are hard constraints: autonomous delivery vehicles have "already reached a fleet scale of tens of thousands, yet are still waiting for a single national pass"[10-79] [third-party verified], and fragmented right-of-way policy

directly draws the commercial boundary of driverless capacity. Technical maturity is not commercial maturity: L4 autonomous trucks have been explored for over a decade without cracking the unit-economics model, and drone delivery runs order volume and losses side by side. Logistics does not lack AI pilots — it lacks the organizational capability and commercial closed loop to turn pilots into systems.

10.7.2 Transformation Paths and Typical Practices

Logistics AI implementation unfolds along five paths, with value realization on the information layer generally faster than on the physical layer.

Express-delivery logistics LLMs are the main battlefield of the top players, which have formed a combined playbook of "vertical LLM + agents + full-chain scenarios" [third-party verified]: Cainiao (Chinese: 菜鸟) launched its logistics customer-service AI brain in 2018; 2023 saw the dense release of "Tianji π" (Chinese: 天机π), JD's (Chinese: 京东) "Super Brain" (Chinese: 超脑), and YTO Express's (Chinese: 圆通) "Zhiduoxing" (Chinese: 智多星); in 2024 SF Express (Chinese: 顺丰) released its "Fengzhi" (Chinese: 丰知) decision-making LLM[10-75]; and in 2025 JD upgraded to "Super Brain LLM 2.0" [official claims]. The strategic divide is clear: direct-operated players (SF Express, JD) self-develop full stacks, while franchise networks use AI tools to penetrate the "headquarters-outlet-courier" collaboration chain — YTO has embedded over 100 agents across its full chain[10-77], with AI roles going through a three-stage upgrade from "agent to AI assistant to digital employee" [official claims + third-party verified].

In warehouse robotics, Amazon announced in 2025 that its global robot deployment surpassed 1 million units, about two-thirds of the world total[10-74] [official claims]; Walmart is deeply bound to Symbotic, spreading AI automation across all 42 regional distribution centers within eight years; UPS aims to raise the share of US packages processed by automation from 66.5% to 68% by the end of 2026 [third-party verified]. Even the giants are advancing incrementally, percentage point by percentage point — transformation is a gradual engineering process, not a one-step "lights-out warehouse."

Smart ports are China's most brilliant logistics calling card. Qingdao Port has built a "smart brain" on its fully domestic, fully autonomous A-TOS/A-ECS systems, with 85 AGVs and 47 yard rail-mounted gantry cranes running unmanned end-to-end[10-73]; Yangshan Phase IV (Chinese: 洋山四期) operates on "F5G ultra-remote control + AGV

automated handling," and the Port of Shanghai (Chinese: 上海港) handled its 50 millionth TEU in November 2025, ranking first globally for 16 consecutive years [third-party verified].

Autonomous delivery advances between scale and losses. In 2025 the industry delivered over 35,000 autonomous vehicles[10-78], and JD Logistics announced plans to procure 1 million over the next five years [third-party verified]; Meituan's (Chinese: 美团) drone delivery has completed over 670,000 commercial orders[10-82] [official claims]; SF's Fengyi "Fangzhou" drone delivers over 20,000 packages per day on average. Digital freight platforms are another kind of story: Full Truck Alliance (Chinese: 满帮) fulfilled over 236 million platform orders in 2025, compressing truck-load matching from hours to minutes; Lalamove (Chinese: 货拉拉) drivers post a 95% on-time rate and a 92% load-matching rate [third-party verified].

Port autonomous driving has already reached industrial scale: as of June 2026, cumulative shipments of autonomous horizontal-transport vehicles for Chinese port operators reached about 2,700 units, with roughly 85% delivered to domestic ports; nearly 40 port areas run batch deployments (10+ units), of which 15 run scale deployments (50+ units). In 2025 alone, shipments were about 850 units (up 70% year over year) with sales of about 1.62 billion yuan[10-135] [third-party verified]. The blue book estimates the global market potential at about 38 billion yuan once port-level autonomous penetration reaches 30%, and over 54 billion yuan at 60% — ports have become the most commercially mature scenario for L4 autonomous driving.

The latest industry-scale figures come from LogClub/Wenda's H1 2026 survey: the applications that can genuinely be verified cluster in high-frequency execution flows such as orders, appointments, carrier communication, freight audit, exception handling, and dock scheduling — flows with clear triggers, system actions, and human escalation points — while large amounts of legacy automation, dashboards, RPA, and chat entry points are repackaged as agents, which is what Gartner calls agent washing[10-163]. Margin pressure is the immediate driver of this wave: 3PL operating margins have fallen from 8.2% in 2019 to about 6.1% in 2024, and clients are starting to treat AI capability as a selection criterion[10-164] [official claims: vendor position].

10.7.3 Benchmark Cases

Qingdao Port: An AI-Native Sample of Physical Heavy Assets [official claims + third-party verified]

Back to the world record at the start. The core is the self-developed A-TOS/A-ECS systems working in concert to form the "smart brain," upgraded with AI large models for algorithms and compute[10-73]. AI-nativeness in ports is a systems-engineering effort of "self-developed foundation + continuous iteration + organizational support," not single-point equipment procurement — this is the most essential difference between physical-bottleneck industries and information industries like finance and media.

Amazon: Robot Army + Central AI Brain [official claims; limited independent verification]

Starting with the acquisition of Kiva in 2012, Amazon expanded over 13 years to 300-plus warehouses and 1 million robots, becoming in 2025 the "world's largest mobile robot manufacturer and operator." Its DeepFleet generative AI dispatch system coordinates robot movement in real time like a "smart traffic management system," reportedly improving fleet operating efficiency by 10% and overall logistics efficiency by 25%[10-74] [official claims]. What deserves attention is not the numbers but the organizational logic: self-development plus acquisitions built the two-tier architecture of "robot army + central AI brain," and the strategic substance is human-robot collaboration and job-skill reshaping.

Full Truck Alliance: An Agent Upgrade for a Digital-Native Species [third-party verified + company disclosures]

The highway freight platform is a natively digital species for which "data is the business," and its evolutionary ladder — information matching (1.0), algorithmic matching (2.0), decision-proxy agents (3.0) — offers a reference template for all platform companies. Full Truck Alliance fulfilled over 236 million platform orders in 2025[10-84]; in 2026 it is embedding agents into real trading-decision scenarios, launching a "cargo-finding assistant" and an "intelligent assistant," and responding to fairness governance with algorithmic disclosure [third-party verified].

C.H. Robinson: turning Lean AI into organizational discipline [third-party verified]: as one of the world's largest third-party logistics providers, it cut nearly a third of its workforce over two years while lifting core business margin from 33.3% to 36.4%; email tender parsing dropped from about four hours to 90 seconds, handling roughly 5,500 orders a day; custom quotes fell from 15–30 minutes to 32 seconds, at about 2,000 a day; LTL freight classification fell from 10 minutes to as fast as 3 seconds, saving roughly 300 hours a day; missed-pickup exception management reached 95% automation with carrier empty returns down 42%; and the supply-chain

audit cycle compressed from four weeks to 25–30 minutes[10-163]. The CEO's framing is even more telling: he calls it Lean AI — refusing technology for technology's sake, with engineers required to walk the floor and find the friction points; the company also offered voluntary buyouts to about 160 middle and senior managers, and acknowledged that **once AI enters the decision, traditional human management nodes become the bottleneck rather than the solution**.

10.7.4 Failure Warnings

TuSimple: The Collapse of a Technology Leader's Commercial Closed Loop [third-party verified]

The "world's first autonomous-driving stock" once had a market value of US$16 billion; it delisted in 2024, and its Guangzhou team was disbanded and liquidated in February 2025[10-80]. Founder Chen Mo admitted that "from 2021 to now, the resources at TuSimple's command could no longer complete the commercialization of autonomous driving." Three root causes: insufficient technical maturity, regulation not ready, and unit economics that never worked — the labor costs saved could not offset sensor and safety-driver costs; layered on top was governance failure from management infighting and strategic flip-flopping. An AI-native organization needs not only technical capability but also a sustainable commercial closed loop and stable organizational governance.

A 95% Pilot Failure Rate [third-party verified]

project44, citing MIT research, notes that 95% of enterprise AI pilots fail to produce measurable returns[10-81] (global AI spending exceeded US$420 billion in 2025). Its conclusion: "it's not a model problem, it's an execution problem" — poor workflow integration, agents lacking operational context, fragmented tools, and unclear accountability. In supply chain the cost is more direct: the handling window for a shipping exception is only 2 hours; once it closes, the enterprise can only choose among expedited premium shipping, damaged customer relationships, and squeezed margins. The root cause of pilot failure lies not in the algorithms but in process integration and accountability mechanisms.

Autonomous Delivery: Scale and Losses Side by Side [official claims + third-party verified]

Meituan's commercial drone orders grew from 670,000 to 900,000[10-82], yet Meituan's new-business segment posted an operating loss of 10.1 billion yuan in 2025 (drones included); the autonomous-vehicle industry delivered over 35,000 units in 2025[10-78], with a market space estimated at nearly 500 billion yuan, yet it is mired in a "selling volume at a loss" price war and fragmented right-of-way. Technical validation is complete, but commercial validation is not — "technical maturity ≠ commercial maturity" is the most expensive tuition logistics AI has paid.

10.7.5 Organizational Patterns and Consulting Takeaways

The physical bottleneck determines the order of value realization. Logistics' 40:60 information-to-physical structure means AI value on the "information layer" — forecasting, scheduling, matching — pays off fast, while "physical layer" automation is a heavy-asset, long-cycle engineering effort. The first consulting move is to clarify which layer the money goes into: the information layer runs on algorithms and data, the physical layer runs on capital and supply chains — the rhythms are completely different.

The data-driven scheduling organization is the core form. Agents are beginning to take on cross-departmental workflows, and organizations are moving from "people + systems" to "people + agent collaboration[10-76]" [third-party verified], with AI roles evolving along "tool → assistant → digital employee." The key proposition for franchise networks is distributed collaboration across "headquarters-outlet-courier," and AI products must lower the threshold to sink down, adapting to the reality of franchisees' uneven digital capabilities — the value anchor of franchise-network AI is organizational collaboration efficiency, not merely replacing labor.

Self-development, acquisition, and supplier binding: three clearly separated routes. Amazon self-develops and acquires; Walmart "spun off self-development and outsourced operations" (selling its robotics business in exchange for over US$5 billion in long-term orders); Cainiao productizes logistics technology for external export (800+ projects globally, 26 Fortune Global 500 clients). Whether an organization must self-develop AI depends on the scale of its data assets and capital strength — "owning AI" and "running an AI-enabled operation" are two equally legitimate choices.

Commercial validation should come first. McKinsey's State of AI 2025 shows 88% of organizations have routinized AI use, yet only 39% achieve significant value and 6% become high-performance winners[10-83] [third-party verified]; the common root of both TuSimple's collapse and drone-delivery losses is large-scale investment before the unit-economics model was validated. Pilots should be tied to business KPIs, not technical metrics.

Talent and the industry foundation come first. The focus of supply-chain competition is shifting from "buying systems" to "building capabilities" [third-party verified], generating new roles such as AI operations, data annotation, and human-robot collaboration supervisors. At the same time, AI-nativeness in logistics is a cross-entity systems-engineering effort — September 2025 saw the release of the first national standard for logistics enterprise digitalization, and the Digital Ship White Paper (COSCO Shipping + China Classification Society) is driving data interconnection across ships, ports, cargo, and people; an industry-level digital foundation is a prerequisite that no single enterprise can complete alone.

Agents are entering the "execution layer" — and what you are really buying is authorization. AI-agent company DeepFabric has signed third-party logistics operator Kenco as a customer with a target of deploying 20 supply-chain agents within 12 months — not a single-chatbot pilot but a portfolio of automated multi-workflow operations[10-136] [third-party verified]. Logistics AI is moving from the "dashboard" (reporting, forecasting, alerting) toward "execution": ingesting inbound events, making decisions autonomously, and writing updates back into core systems, with deployments reaching deep into the TMS and last-mile fulfillment-orchestration layers. The real constraints on such deployments are data permissions, integration scope, and exception-handover rights — when a vendor sells you "agents," the hidden purchase is authorization: what the software is allowed to change without asking.

Leading logistics companies have already shifted their organizational assumption from "AI as an assistive tool" to "AI executes, people judge." DHL Group's new *Logistics Trend Radar*, released in September 2026, concludes that AI, robotics, and automation are changing not only how logistics work is done but the workforce itself, while logistics remains a "people-centered" industry in which human judgment sits at the middle — and it places this edition's emphasis on the change that "technology has entered the execution layer"[10-224]. The transmission path is direct: job design, training systems, and shop-floor management must all adjust. A companion DHL piece focuses on the workforce side — wearable sensors,

collaborative robots, remote operation, and AI work assistants are changing what practitioners do every day, and **once technology enters the execution layer, the organizational bottleneck shifts from "do we have a model" to "can the people on site work with it"**[10-224].

Replacement pressure in last-mile delivery now has concrete gradations. JD Logistics (Chinese: 京东物流) announced a five-year procurement plan covering three million robots, and China's annual sales of unmanned urban delivery vehicles are projected to reach 89,000 units in 2026, with "four million couriers" used as a scale reference for those potentially affected[10-225]. The value of the piece is that it pulls unmanned delivery out of the technology-demo frame and back into an organizational question: as robots take line-haul and in-campus transfer and unmanned vehicles take urban delivery, couriers' work narrows toward the last hundred meters, doorstep scenarios, exception handling, and customer interaction. **The number of jobs and the content of jobs change simultaneously — and the latter usually happens first.**

"Will it be replaced" is the wrong question; "in what order" is the right one. An analysis of back-office functions in logistics companies lays out a clear sequence: standardized roles go first, decision-making roles sit in the middle, and roles requiring cross-departmental coordination and interpersonal judgment go last. Back-office functions (customer service, documentation, reconciliation, reporting, planning) are the most standardized and the first to be compressed, while roles such as dispatch, exception handling, and customer relationships are first "augmented" and only then redefined in scope[10-226]. **Turning replacement from a binary judgment into a sequencing question is what allows an organization to do something more valuable: move the people who are freed up into the later-stage roles before the compression happens. Logistics AI competition is unfolding along two routes at once: "building your own capability" and "platform execution engines."** C.H. Robinson exemplifies the "Lean AI" build path: a team of 450 software engineers and data scientists develops AI models and agents in-house (rather than buying), and its self-built "Always On Logistics Planner" orchestrates hundreds of interconnected agents across the full freight lifecycle, with the company claiming more than 100 trillion proprietary logistics data points; its retrospective analysis of truckload AI workflows from January 2024 to January 2026 claims a "statistically significant" relationship between two more-mature agents and better customer-operations outcomes (without disclosing the coefficient)[10-262]. **Its organizational**

meaning is to "connect the intelligence of adjacent steps rather than stacking automation in isolation" — AI's value comes from process-level orchestration, not point tools. Flexport represents the other route: its Winter 2026 release upgraded the platform from a "visibility layer" to an "automation and execution engine," using AI agents to audit historical customs filings for compliance (the company says error rates fell to 0.2%, about a tenth of the industry benchmark) and an optimization engine to evaluate every booking (up to 10% freight savings, recommended for execution with "in-platform human approval"), while cutting notification volume by about 80% (keeping only true exceptions)[10-263]. **What the two routes share is that the human role moves back: from operator to approver and exception handler.** But how far to authorize remains cautious across the industry — a RELEX survey of 500-plus supply-chain leaders found "high confidence, low delegation": 67% have more confidence in AI than last year, but only 10% are willing to let AI make key decisions without human review, and 54% prefer to keep humans in the loop[10-264]. Chinese samples were dense at the 2026 CIFTIS: YTO Express (Chinese: 圆通) released "six full-stack AI achievements" (digital twins covering all network hubs cut unloading wait time 25%, its self-built "Zhiduoxing" model drives 100+ agents, and 28 digital employees take on repetitive work across ten domains), SF Express (Chinese: 顺丰) showed its "Baichuan technology platform" and "Apu AI agent cluster," and STO Express (Chinese: 申通) displayed its agent platform "SClaw" and launched an "AI ecosystem partner program"[10-265]. **The courier industry's long-term competitiveness is revealed by R&D intensity**: in 2025 JD Logistics invested RMB 4.136 billion in R&D (1.90% of revenue) and SF Express RMB 2.96 billion (0.96%), while YTO invested RMB 249 million (0.33%) and Yunda RMB 276 million (0.54%) — analysts judge the gap "may translate into a substantive divergence in operating efficiency and cost structure within three to five years"[10-266].

Logistics' gap can be stated in one set of numbers. BCG's survey of 30 leading global logistics companies shows 97% rank AI a strategic priority, 70% have an AI strategy and 67% have dedicated budget, but **only 13% believe AI has delivered measurable financial impact**; by experience, algorithms are only 10% of the work, technology and data 20%, and the remaining 70% is people and organizational change[10-300]. The same study's three-level maturity ladder is useful — point tools, tools coordinated within one process (a customer-service agent calling live rates to complete a quote), and a cross-organization connected autonomous enterprise that nobody has reached — with the organizational prescription being a

"federated operating model": a lean central hub owning standards, platforms and value measurement while business units carry their own P&L. The center of gravity is also shifting: an operations and supply-chain survey shows AI-enabled tools moving from peripheral pilots into backbone processes, with planning and forecasting at 66% and sourcing and procurement at 64%[10-301] — precisely the areas that most depended on veteran planners' judgment and were hardest to standardize. **This is also why, once logistics AI enters the backbone, it immediately becomes an organizational problem rather than a technical one. "AI-directed logistics" is now a product, not a demo.** JD Logistics' 2026 ChaoNao 3.0 provides a complete structure: five specialist models — PreX for volume and supply-demand forecasting, OptiX for warehouse layout, inventory allocation and vehicle scheduling, OmniX for image and video recognition, GeoX for computing across addresses, routes and time, plus a module for coordinated dispatch. On results, route planning for hundreds of millions of parcels compressed from minutes to seconds, automated vehicle scheduling reached 86%, and JD Logistics posted RMB 124.7 billion of revenue in the half year[10-315]. **The real barrier is not any single model but the assembly of forecasting, optimization, vision and geospatial models into one decision pipeline — and the dispatcher's role shifts from issuing instructions to reviewing exceptions, which is what role consolidation in 4.9 looks like in logistics.**

The time scale of network-level dispatch has been rewritten by the digital twin. UPS is building a real-time digital twin of its global network — more than 200 countries, air and ground networks, end-to-end parcel flows — refreshed every 10 minutes, alongside an agentic control tower, end-to-end RFID tracking and AI customs clearance that the company says clears 97% of shipments on the first day. The "Network of the Future" program commits $9 billion over five years and is expected to yield $3 billion of recurring annual savings; Happy Returns, the reverse-logistics company it acquired, uses AI against return fraud[10-316]. The significance goes beyond visualization: the twin moves network-level dispatch from post-hoc review to re-optimization every ten minutes, changing the operating tempo and the response cycle of the chain of command rather than merely the tooling. Set this against the finding in 9.4 that most supply-chain AI stalls halfway: the projects that do run usually closed the command loop first.

10.8 Healthcare

10.8.1 Industry Profile and Bottleneck Triage

Between October 2023 and December 2024, TPMG (The Permanente Medical Group) — part of Kaiser Permanente, one of America's largest healthcare groups — did something big: across 17 medical centers in Northern California, it deployed "ambient AI clinical documentation" (Chinese: 环境式 AI 病历) for 7,260 physicians — AI that listens to the doctor-patient conversation and automatically generates the medical record. Across more than 2 million patient visits, physicians collectively saved 15,700 hours of documentation time, and 84% said the AI improved their connection with patients[10-85] [third-party verified, NEJM Catalyst]. It is one of the largest generative AI deployments in medical history, and a sample of the most correct posture for medical AI: not replacing doctors, but doing the doctors' work for them.

Healthcare is a typical information-physical hybrid industry: diagnosis, medical records, and image interpretation are essentially information processing, but treatment outcomes ultimately land on physical actions — surgery, medication, nursing — putting the information:physical ratio somewhere around 30-50:50-70. This determines that medical AI cannot digitally rewrite the entire process the way finance can; it can only be embedded in an "augmenting people" rather than "replacing people" mode. Grand View Research projects the global healthcare AI market will grow from US$36.7 billion in 2025 to US$505.6 billion by 2033 [third-party verified].

But the growth narrative masks four structural contradictions. Regulatory compliance comes first: the FDA has approved over a thousand AI/ML medical devices, yet no generative AI has received FDA approval[10-93]; in China, Class III medical device registration certificates are the precondition for AI to enter clinical billing — United Imaging (Chinese: 联影) holds 16, Deepwise (Chinese: 深睿) and Shukun (Chinese: 数坤) 14 each, and Infervision (Chinese: 推想) 13 — and the number of certificates directly constitutes a moat [third-party verified]. Second is clinical accountability: once AI enters high-risk operations, liability division is far from mature — US surgical robots caused 1,391 incidents and 144 patient deaths over 13 years[10-95] [third-party verified]. Third is data privacy: in November 2025 the WHO warned of a serious gap between medical AI expansion and legal-ethical safeguards [third-party verified]. Fourth is embedding into physicians' workflows: AI alone can reach 90% diagnostic

accuracy, but when doctors use it as assistance, accuracy rises only about 2 percentage points [third-party verified] — the gain from human-machine collaboration depends on process design and trust building, not model accuracy.

10.8.2 Transformation Paths and Typical Practices

Three paths are clearly separated.

Chinese hospitals take the route of "open-source models + local deployment + hospital-wide infrastructure." The DeepSeek open-source release in early 2025 significantly lowered the AI threshold for hospitals: Shenzhen Nanshan Hospital (Chinese: 深圳南山医院) deployed DeepSeek-R1 671B locally within 72 hours; The University of Hong Kong-Shenzhen Hospital (Chinese: 港大深圳医院) deployed it on a "data never leaves the hospital" basis; and Peking University Third Hospital (Chinese: 北大三院) combined multiple deployment modes for hospital-wide coverage [third-party verified]. Scenarios are spreading quickly: West China Hospital (Chinese: 华西医院) released two agents built on its "Huaxi Hongyi" LLM (Chinese: 华西黉医) — patient companionship and medical documentation — and the documentation agent has generated nearly 600,000 medical records since launch [third-party verified]; AI has penetrated appointment triage, medical insurance cost control, DRG grouping, and pharmacy review across the entire process. On the budget side, we have entered the "infrastructure era": Zhongshan Hospital's (Chinese: 中山医院) 160 million yuan AI platform tender has landed, and hospital AI budgets have jumped from the millions to the hundreds of millions [third-party verified]. IDC estimates China's AI + healthcare application software market at 3.54 billion yuan in 2025, projected to reach 14 billion yuan by 2030, and judges that the watershed has shifted from "how strong is the model" to "how deeply can business flows be redesigned" [third-party verified].

US hospitals take the route of "administration first, clinical caution, portfolio governance." HCA (191 hospitals) advances in layers: on the clinical side it partners with Google to optimize nurse handoffs; on the operations side, nearly 100 hospitals have deployed scheduling and workforce tools; and administration is treated as the area with the "shortest value path." Its CFO admitted that "rolling out AI incrementally and changing frontline behavior is far harder than imagined," and the investment focus is shifting toward change management [third-party verified]. Mayo Clinic will invest more than US$1 billion over the next few years across 200-plus initiatives; Advocate Health uses an "evaluation funnel" (225 proposals → 40 use cases) for centralized selection [third-party verified]. A Menlo Ventures survey of 700-plus US

healthcare executives found the industry deploying AI at 2.2x the speed of other industries, with healthcare AI spending of about US$1.4 billion in 2025, roughly 3x the prior year[10-92] [third-party verified].

AI drug discovery is reshaping the paradigm. Insilico Medicine (Chinese: 英矽智能) uses generative AI across the entire pipeline from target discovery to clinical development, closing 13+ business-development deals in 2025 with cumulative potential value exceeding US$10 billion[10-96] [third-party verified]; its CEO claims AI can compress the drug R&D cycle to about one year (a candidate drug in as little as 9 months, versus about 4.5 years traditionally) [official claims; "candidate drug" ≠ "drug on the market"]. On the regulatory side, the FDA published final guidance on PCCP (Predetermined Change Control Plans) in August 2025, allowing AI algorithms to iterate continuously within predefined ranges without reapplication[10-93] — this "learning license" system raises the organizational bar for continuous monitoring and change management [third-party verified].

The deployment list in healthcare is also lengthening. AI Weekly's compilation of 21 real deployments aggregates verifiable cases by industry, including one where the UK's NHS is running a WhatsApp-based AI agent to reduce missed appointments[10-166] [third-party compilation] — source-linked lists like this are the most practical way to separate vendor promotion from genuine deployment. On the academic side, a paper in the *Nature* series uses AI to predict clinical deterioration in a post-acute hospital, extending early warning from acute settings into low-resource environments long lacking effective warning tools, and anchoring evaluation on outcomes rather than model performance — filling the outcome-oriented gap in the consensus that model performance does not equal clinical value[10-165] [third-party, academic]. The newest organizational form in Chinese healthcare AI is turning top-tier hospital capability into a deployable model. Fu Chaoqi, director of the National Healthcare Security Administration's big-data center, argues that global AI competition is shifting from a technology contest over compute and foundation models to a scenario contest centered on agents, and that the "personal medical insurance cloud" pilot launched in 2026 aims to integrate members' data scattered across hospitals, pharmacies and wearables into a national health agent covering 1.33 billion insured people (for comparison, U.S. Medicare covers about 65 million and the UK NHS over 60 million). Its security architecture is the most instructive part: "AI iterates inside the domain, data never leaves" — health data is not handed to AI companies for training; agents are deployed inside the medical-insurance data platform's own domain for

computation, training and iteration, exporting only service results in accordance with the law, on an architecture of "1 national platform + 32 provincial platforms + N application scenarios"[10-193]. Cross-institution task re-division is happening too: at the Huawei Cloud INSPIRE conference the first 20 hospitals joined the smart-healthcare zone, spanning top-tier tertiary hospitals and a range of prefecture- and county-level ones; Handan Central Hospital — about 150,000 pathology slides a year, 600-700 on a single day, with heavy physician workload — formed a regional digital pathology consortium with county hospitals in Wu'an, Shexian and Daming, exporting the central hospital's diagnostic capability down to the counties[10-197]. **AI changes where capability lives, not just how fast work moves: instead of dispatching experts, it packages judgment into deployable models and processes.**

10.8.3 Benchmark Cases

Kaiser Permanente: Ambient Documentation for 7,260 Physicians [third-party verified, NEJM Catalyst]

Back to the deployment at the start. Physicians collectively saved 15,700 hours of documentation time, with after-hours documentation time averaging 1.03 minutes less per visit; 84% of surveyed physicians said AI improved their connection with patients, and 82% reported higher job satisfaction[10-85]. Combined with Abridge's deployment across 40 Kaiser hospitals and 600-plus clinics, ambient documentation has become the most commercially mature track in medical AI. But the Peterson Health Technology Institute also cautions: financial returns to the system have not yet been validated at scale, and scaling depends on deep EHR integration and safety-monitoring systems.

Zhiyi Assistant: 1.2 Billion Assistance Sessions Across Primary Care [third-party verified / official disclosures]

iFlytek's (Chinese: 科大讯飞) "Zhiyi Assistant" (Chinese: 智医助理) embeds "AI-assisted diagnosis + standardized electronic medical records" into grassroots workflows. As of the end of 2025 it covered over 800 districts and counties across 31 provinces and more than 77,000 grassroots medical institutions, with over 1.2 billion cumulative assistance sessions serving more than 250,000 primary-care physicians[10-86] [third-party verified figures]; Liu Qingfeng disclosed that Anhui alone corrected 170,000 misdiagnoses in a single year [official claims]. Its organizational

form — "province-level coordination, government-funded, system-embedded" — validates a path to grassroots accessibility while exposing its dependence on data quality and government funding.

Beijing Anzhen Hospital: The "Report Revolution" of Operations-Management AI [third-party verified]

Released in March 2026, China's first "public hospital operations-management large model" was developed with China Telecom over seven months, integrating the HIS, SPD, and ODR systems, drafting 200-plus data standards, governing 3 million-plus data records, and establishing 800-plus core management indicators. Operations-management report generation has been cut from days to 5 minutes, management response speed improved by 95%, and precision decision-making efficiency improved by 60%[10-88]. It represents hospital AI extending from clinical assistance to operational decision-making, rebuilding management's data-decision infrastructure.

Ambient scribes, new evidence: time savings are "modest," burnout drops sharply. [academic research] The first large multicenter study in JAMA Network Open (6 U.S. health systems; 263 outpatient physicians and advanced practice providers; the Abridge platform; 30 days) found the share of doctors reporting burnout fell from 51.9% to 38.8% (adjusted odds of burnout down 74%), with significant reductions in documentation-related cognitive load and after-hours charting time — yet additional patient visits showed no statistically significant difference[10-137]. A sister study (5 academic medical centers; 8,581 clinicians) likewise found AI ambient documentation tools associated with only "modest" reductions in EHR time and no significant change in off-hours use, with the benefits concentrated among primary-care physicians, advanced practice providers, and women[10-138]. The first tranche of returns lands in employee experience and retention, not capacity — hospital purchasing decisions should measure "objective time" and "subjective experience" separately.

Meizhong Airui: writing AI into the hospital itself from the design stage. [third-party] Caixin Weekly reports that Beijing's Meizhong Airui Cancer Hospital (Chinese: 美中爱瑞肿瘤医院) is building a new campus — total investment around 6 billion yuan, planned at 800 beds — with the stated goal of becoming China's first "AI-native" physical hospital: agents bound to no single system or scenario, but pervasive across the building, medical devices, and information systems, covering all key business areas and forming a "collaborative ecosystem" with human staff[10-139]. This is a rare organizational experiment that writes AI into the hospital's ontology at the

design stage — architecture, procurement, information architecture, roles, and processes rebuilt in sync — and its outcome will test whether the "AI-native" concept can hold in a heavily regulated, high-accountability medical environment. **Yonsei University Health System: embedding agents in the tools staff already use [third-party verified]**

Led by its Center for Digital Health Strategy, Yonsei University Health System deployed Copilot and Copilot Studio agents inside its existing Microsoft Teams for nursing and administrative support tasks rather than high-risk clinical decisions. Three design choices are emphasized: no separate AI portal — agents live inside everyday collaboration tools, lowering adoption friction; a SaaS and low-code route (Copilot Studio plus Power Platform) so the system evolves through configuration rather than repeated engineering; and a "citizen developer" model in which IT owns policy, security and infrastructure guardrails while departments build agents around their own documents and frequent questions. The first use case was a nursing-guideline Q&A agent consolidating hospital standards and departmental references from different formats into a single view. The article records an underrated organizational variable: AI did not fix bad documentation, it exposed documentation quality — documents that are intuitive for humans can still be hard for AI — which means knowledge management must be upgraded from a cleanup task to a strategic function[10-195]. **The real question it poses is not how many agents can be built, but whether the institution can form the habits that maintain them — document governance, structured frontline feedback, and an owner for every knowledge domain.**

10.8.4 Failure Warnings

HIMSS 2025: 80% of Projects Fail to Realize Value [third-party verified]

A HIMSS panel discussion confronted the industry's pain point directly: 80% of healthcare AI projects fail to realize value conversion; 97% of organizations agree deployment is urgent, but only 14% have effective implementation capability[10-89]. Its verdict cuts to the chase: "AI failures are not about immature technology but about strategic mistakes" — and the biggest mistake is trying to solve everything at once.

NHS: The Implementation Chill on a National Program [third-party verified]

UCL, with the Nuffield Trust, evaluated NHS England's £21 million AI chest-imaging program across 66 hospital trusts: contract signing was delayed 4-10 months, and 18 months after contract completion, 23 of 66 trusts (a third) still had not used it in clinical practice[10-90]. The obstacle is not algorithms but organization: overworked clinicians cannot participate, aging heterogeneous IT systems are hard to integrate, and senior doctors worry about accountability for AI-informed decisions.

Hallucination and the Clinical Adoption Gap [third-party verified]

Medical LLMs inherently carry hallucination risk, and the industry consensus is that it "cannot be eliminated entirely, only managed and corrected." AI alone reaches 90% diagnostic accuracy while physician assistance adds only about 2 percentage points — without process design and trust building, accuracy does not automatically translate into treatment outcomes. The 1,391 incidents and 144 deaths from surgical robots over 13 years[10-91] are a reminder that AI's rollout into high-risk clinical operations is far slower than in administrative scenarios. An HFMA survey shows nearly 70% of CFOs admit governance maturity lags adoption speed, and the resource misallocation of "bought but unused, used but unevaluated, evaluated but never retired" is happening now [third-party verified].

UnitedHealth: when algorithmic decisions lack human review. [third-party verified] The families of two deceased Medicare Advantage beneficiaries have sued UnitedHealth, the largest U.S. health insurer, alleging it knowingly used flawed AI systems (such as nH Predict) to deny post-acute care that physicians deemed necessary — a financial arrangement of "collecting premiums while not paying claims." The complaint argues the insurer systematically denied claims because only about 0.2% of enrollees were expected to appeal AI decisions, and cites earlier class-action materials claiming over 90% of AI denials were overturned on appeal[10-140]. A federal judge in Minnesota has ordered UnitedHealth to hand over internal AI review-committee documents and related performance and compensation records. When algorithms are embedded in claims decisions without transparency or human review, an efficiency tool metastasizes into systemic compliance and ethical risk — a complete lesson in healthcare-AI governance failure. **Sociotechnical misalignment: the failure mechanism, from academic evidence.** A qualitative case study published in JMIR in 2026 examines sociotechnical misalignments in hospital AI implementation — deviations caused when technical systems fail to align with existing workflows, role divisions and organizational routines[10-194]. Industry reporting covers commercial and process obstacles; the academic work supplies the mechanism:

misalignment is not a one-off deployment error but ongoing tension among technical capability, organizational routine and accountability structures. On governance, a review in the Party School's Study Times lays out four risk categories and the rules now taking shape — data security (agents with too broad access, cross-comparison among multiple agents inferring sensitive information), algorithmic safety (training-data bias producing systematic misdiagnosis or missed diagnosis in specific populations, and black-box outputs eroding clinician trust), behavioral drift (overstepping to prescribe medication or tests, inducing unnecessary spending for commercial gain, algorithm-steered care), and allocation of liability (gaps among developers, users, medical institutions and algorithms). On rules, the Expert Consensus on AI Application and Governance in Medical Institutions (2026), jointly drafted by more than 40 organizations, proposes tiered admission (simplified filing for low risk, medical-device regulation for medium risk, the strictest standards for high risk), a one-vote veto for high-risk products, six-month real-world studies of local performance with competitive cross-validation, and refusal of exclusivity agreements; U.S. CHAI and the Joint Commission's guidance on responsible AI use in healthcare, with eight accompanying governance handbooks released in May 2026, cover organizational AI policy, structure, resources and processes and emphasize keeping a human in the loop. The article also cites WHO's April 2026 assessment of the EU: among the 27 member states, 74% already use AI-assisted diagnosis and 63% use chatbots, yet only 11% have a dedicated health-sector AI strategy — **governance lagging behind adoption is the common shape of healthcare AI worldwide.** [10-196]

10.8.5 Organizational Patterns and Consulting Takeaways

The "AI alert → human confirmation → intervention" organizational loop is the value amplifier of clinical AI. UCSD's COMPOSER cut in-hospital mortality by 17%[10-94], and Augusta Health, a community hospital, saved 282 lives in two years on the same path — what they share is not a stronger model but embedding alerts into care workflows, training response mechanisms, and continuously calibrating the model. The takeaway for small and mid-sized hospitals: enter through a single high-value scenario and use organizational mechanisms to compensate for resource disadvantages.

Change management is the main bottleneck, not technology. A McKinsey survey shows 50% of healthcare organizations have implemented AI, but concludes that "the main bottleneck is not technology but leadership and organizational change" — corroborated by the NHS research; HCA's CFO put it bluntly: changing frontline behavior is far harder than deploying tools.

Physician-adoption design determines the ceiling. Kaiser's high satisfaction came from embedding AI into existing workflows rather than adding burden; HIMSS emphasizes that "unexplainable AI decisions will lose clinician and patient trust." Consulting takeaways: do workflow analysis before model selection, and build trust from administration to clinic.

Regulation first is a roadmap, not a barrier. Class III certificates, FDA approval, algorithm filing, and data security assessment form a landscape where "the entry barrier is organizational capability": certificate counts become a moat[10-87], buyers need new validation and acceptance capabilities, and third-party evaluation standards are becoming the common language of all parties.

Data assets, not models, have become the biggest shortfall. The consensus at the VB100 conference: the biggest shortfall is no longer compute and models but standardized, high-quality data assets. The essence of healthcare AI-native transformation is synchronously rearranging four things — clinical workflows, management decisions, regulatory compliance, and data governance. The hardest part technically is keeping AI from overstepping before the physician signs off; the hardest part organizationally is getting AI genuinely used after the signature.

The practical dilemmas of healthcare AI in 2026 were broken into five exam questions at one professional conference. On top-level design, Shi Rui of West China Hospital warned against copying the traditional IT playbook and letting departments build in silos into a new set of "AI chimneys," arguing instead for a unified foundation across data, computing, and models, preferring smaller models for narrow scenarios, and cautioning that a specialty may pilot first but "a single point application must not become the endpoint of construction." Zhang Jiyang of Zhongshan Hospital, Fudan University, noted that "the evidence proving that medical AI tools create value remains very limited" and warned against worshipping AUC and other laboratory metrics. Wang Lihua of Beijing Friendship Hospital suggested starting AI coding with low-risk scenarios — back-office administration, research assistance, business assistants, API integration — rather than inserting it directly into core clinical decisions. Niu Chen of the First Affiliated Hospital of Xi'an Jiaotong University framed it

as "the algorithm sets the performance ceiling, systems integration sets the floor for clinical deployment." And the First Affiliated Hospital of Ningbo University used "AI alerts plus physician credits" for pre-emptive warning and passive quality control, stressing that AI is only an assistive tool while clinicians and management carry final accountability[10-228]. Two industry predictions are worth recording as well: more than 60%–70% of in-hospital software can in future be developed in-house, and the buildout of agents will gradually shift to clinicians, with vendors retreating to model engineering, workflow orchestration, and multimodal data foundations.

The ICU provides a quantified sample of "entering the workflow." At Peking University Shenzhen Hospital's ICU, assembling a picture of a critically ill patient once required two to three hours of pulling 72 hours of bedside monitoring data, lab reports, imaging, and hundreds of orders; Mindray (Chinese: 迈瑞)'s "Qiyuan" critical-care model produces a complete timeline in five seconds and raises an alert. Its verifiable results: it can identify sepsis shock and other critical risks six hours earlier; without increasing headcount, critical-care discharges rose 13% and average length of stay fell 12%; and the commercial model charges per bed, with the large-model subscription alone reaching tens of millions of yuan a year[10-229]. **The organizational meaning is not in the algorithm but in a change of language: over the past few years China produced hundreds of medical large models whose MedQA scores even exceeded average human physician performance, yet their application-side results won no endorsement — "a model with flashy parameters does not necessarily know how to treat patients"; from 2026, vendors stopped competing on parameters and started competing on who can genuinely enter the hospital's and the physician's workflow.**

When evaluating AI's organizational returns, do not omit retention. Among the cases compiled by Becker's, Sanford Health found that ambient AI documentation markedly improved staff satisfaction and retention: less than a year in, 88% of clinicians reported reduced burnout or fatigue and 95% said it helped relieve mental strain[10-230]. Parkview Health's key phrasing was that AI is "no longer an experiment but an operational project with explicit outcome goals" — by January 2026 the system was processing three million AI tokens a month, versus 60,000 a few months earlier[10-230]. **The criteria for "from pilot to operational project" thus become actionable: a named outcome goal, a process metric (usage volume), and an attributable organizational result (burnout rate, retention).**

But healthcare's real barriers are all institutional. An analysis of 2026 competition in medical large models notes that the core of competition is shifting from "model capability" to "scenario embedding" and from "answering questions" to "executing tasks," while constraints cluster into four categories: data barriers, process constraints, liability boundaries, and payment mechanisms[10-231]. **If any one of them remains unsolved, no matter how strong the algorithm is, it will stay at the demo layer — all four barriers are organizational and institutional problems, and none can be solved by upgrading the model. The healthcare AI narrative has moved from "bolting tools onto hospitals" to "rebuilding hospitals around AI," but all four landing barriers are institutional.** The 2026 World Digital Health Forum released the world's first *International AI Hospital Consortium Consensus*, defining an "AI hospital" at the international level as "a new paradigm of smart health driven by service twins," clarifying that it is neither a "virtual hospital with no real doctors" nor a traditional hospital "with a few AI tools added," but a rebuilding of an integrated online-offline health system with AI as the core driver; the consensus lists five core traits (paradigm innovation, service twins, virtual-physical synergy, fused ecosystem, proactive care), with "paradigm innovation" stressing AI as the underlying logic from the design origin — i.e., "AI-native"; yet the consensus concedes this remains an ideal form, needing at least 3–5 years for full realization[10-267]. **The most tangible scale result is the regional platform**: Guangdong has built an assisted-diagnosis platform covering 2,257 medical institutions province-wide, completing more than 270,000 AI-assisted image reads, with accuracy above 98% for seven categories of imaging diagnosis and an hourly read volume equal to a full day's work of 150 radiologists at a tertiary hospital[10-268]. **The barriers to the "last mile" were grouped by CCF YOCSEF Hangzhou into four kinds**: data foundation (not a lack of data, but difficulty in screening and standardization, inconsistent formats across institutions, and un-unified regional standards), technical capability (models degrade when generalized across institutions, and limited explainability weakens clinician trust), institutional mechanism (AI is an assistive diagnostic tool, and legal liability is a vacuum), and commercialization (no mature payment or revenue-return model)[10-269]. **Clues to organizational solutions are also emerging**: UC San Diego Health built a deeply inclusive AI governance model whose structure includes IT, HR, physicians, nurses, compliance, legal, ethics, and operations leadership, with the lesson that "AI governance is technical oversight, but even more, organizational alignment"[10-270]; the AHA's *2026 Health Care*

Workforce Scan sets the tone — leaders are rethinking workflows and redesigning care teams to lay the foundation for more return from AI investment, with about 40% of surveyed US community hospitals reporting AI or machine-learning use[10-271].

Healthcare's organizational answer first appeared in a new role. Several leading health systems created chief AI officer (CAIO) roles around 2024, and the job is in practice more "chief skeptic" than AI evangelist — one interviewee describes the posture as "we can try it, and if it doesn't work we stop," and another cites Amara's law to remind everyone that "real transformation is cumulative, not instantaneous"; the shared hidden ceiling is data readiness: prototypes take hours, whereas making the underlying data accurate and the outputs reliable takes far longer, and training one clinical-workflow agent required reviewing thousands of work instructions accumulated over a decade[10-302]. Evidence on outcomes is accumulating too: a 13-month phased-rollout study extended ambient AI documentation from outpatient-style settings into the emergency department's high-intensity, unstructured environment, providing peer-reviewed evidence on whether ambient documentation saves time and where it works better[10-303]. **Healthcare's lesson transfers to other heavily regulated industries: establish the role that can say no before discussing scale.**

Healthcare AI's downward spread makes "embedded in the workflow" a condition of entry. In 2026 clinical models accelerated into county-level institutions, and the capability boundary expanded from imaging reads to record quality control, assisted consultation, pathology diagnosis, treatment-plan recommendations and literature search. Shuyang Hospital in Jiangsu embedded an AI clinical decision-support system into physicians' workstations: outpatient penetration reached 46.1%, AI completed record logic checks with a 99.5% closed-loop quality-control rate, and system response time fell from 54 seconds to 8. RuiPath 2.0, released by Ruijin Hospital with Huawei Cloud, runs a device-cloud split so a lightweight version does minute-level inference on an ordinary PC and a county hospital needs only a digital scanner; more than 90 hospitals are live nationwide, and the subscription model pulls first-year investment down from the millions a self-built pathology digitization system would require[10-318]. **This round of evidence comes from the grassroots rather than the top-tier hospitals, and it shows that "can it enter the doctor's daily actions" decides success more than "how strong the model is."** None of the four barriers has disappeared — zero tolerance for hallucination, data-compliance

thresholds, the vendor/hospital/physician liability boundary, and how insurance pays for AI services; if anything, going downstream amplifies the liability question, because what county hospitals lack most is precisely the person able to review the AI's output.

10.9 Manufacturing

10.9.1 Industry Profile and Bottleneck Triage

Let me start with a true story. A textile mill in the Yangtze River Delta (Chinese: 长三角) spent 3.7 million yuan on an AI fabric inspection system — machine vision to spot defects on the cloth surface, theoretically faster and more accurate, and capable of replacing a dozen-odd QC workers. After the system went live, the problem turned out to be the fabric itself: surface reflection sent the machine's misjudgment rate as high as 15%[10-101]. The boss did not dare let the machine make the call, the veteran inspectors' manual re-checks continued as before, and the AI went from "replacement" to "assistant" — the return on investment fell far short of expectations [third-party verified].

This story almost condenses every contradiction of AI in manufacturing. Of the ten industries written in this chapter, manufacturing is probably the most contradictory one: McKinsey ranks it the area with the greatest value potential from generative AI (up to 2x productivity gains for manufacturing and supply chains, with nearly 70% of tasks automatable), and nearly a quarter of China's roughly US$2 trillion generative AI value comes from here[10-99]; yet at the same time, it has the highest physical bottleneck of any industry in this book — an information:physical ratio of only about 20-40:60-80. In plain words: **most of the work on the shop floor is machine cycle times, material flows, and equipment wear — things you can see and touch — and no matter how clever the algorithm, it cannot outrun the machine tools.**

The gap between big potential and hard implementation comes down to three things. First, AI speeds up the decision layer, not the physical layer — it can help you compute production schedules, review reports, and draft process documents, but it cannot make the machine tools turn faster. Second, industrial data is naturally siloed: equipment protocols each speak their own language, and SCADA, ERP, and MES each form their own systems; the most extreme case is defect samples — hundreds of thousands of photos of good products but only twenty-some defective ones, which still

have to be labeled one by one by veteran workers on the verge of retirement. Third, the numbers do not add up: a Deloitte survey shows 91% of industrial AI projects fell short of expectations, and 90% of those failures were not technical problems[10-100].

10.9.2 Transformation Paths and Typical Practices

AI implementation in manufacturing roughly unfolds across five layers, from the "visible single points" to the "invisible organization."

The first layer is lighthouse factories, solving the demonstration question of "what AI can actually do." China leads the world in lighthouse factories — Haier (Chinese: 海尔) has 13 in total, and Foxconn (Chinese: 富士康) has 5 factories on the network[10-105]; McKinsey data shows nearly 60% of use cases at newly designated lighthouses already leverage AI, with 2-3x productivity gains, 99% defect-rate reduction, and 30% energy improvement. The real value of lighthouse factories is not the technology but the methodology: Foxconn codifies its experience into white papers and extends toward a "lighthouse industry," while Haier empowers external companies through COSMOPlat (Chinese: 卡奥斯).

The second layer is industrial LLMs, which Huawei (Chinese: 华为) calls the future "operating system" of manufacturing. Industrial LLM penetration in China is projected to reach 50% by 2030, with the market surpassing 42 billion yuan[10-106]. Players split into two routes: big tech (Baidu, Huawei) and "industry columns" — COSMOPlat's "Tianzhi" (Chinese: 天智), the Digital Building Materials Research Institute's (Chinese: 数智建材研究院) "Xiaomiao" (Chinese: 晓妙), and Zhonggong Hulian's (Chinese: 中工互联) "Zhigong" (Chinese: 智工).

The third layer is industrial agents, pushing AI from "demonstration" to "production." 2025 has been called the "year one of industrial agents" — CCID Consulting (Chinese: 赛迪顾问) data shows China's agent market at 7.84 billion yuan that year, expected to reach 13.53 billion yuan in 2026; 2026 enters the "replication era," where the challenge shifts from technology to engineering.

Institutional reports made this path clearer in 2026. Jazzyear's *2026 Industrial AI Agent Research Report* judges that industrial agents are not a direct replacement for traditional industrial software such as ERP and MES, but an **intelligent operations layer** built on top of the existing digital foundation. It proposes a factory-native mechanism — agents must grow out of real production flows, real industrial data, real execution processes, and real business outcomes, so that **the factory is**

simultaneously the deployment site, the training ground, and the validation ground; the competitive focus shifts from single-point model capability to AI-native depth plus end-to-end factory closure, with scheduling, process optimization, execution monitoring, and equipment maintenance as the priority scenarios[10-167] [third-party, institutional report]. CCID's dedicated report, meanwhile, frames industrial-agent deployment as resting on three links — compute resources at the bottom, platform frameworks in the middle, and vertical applications on top — offering a value-chain view for judging where the money settles[10-168] [third-party, institutional report].

The fourth layer is the two single-point scenarios with the clearest ROI: AI quality inspection and predictive maintenance. AI vision inspection is the fastest-penetrating scenario (China's smart-inspection output reached 574.5 billion yuan in 2025), with vendors claiming missed-detection rates cut to 1% of manual levels and 70% savings on re-inspection costs [official claims]; on predictive maintenance, IBM, citing ISA data, says factories typically lose 5%-20% of manufacturing capacity to downtime, and AI can cut unplanned downtime by 30%-50% [vendor claims]. But both paths share the same stumbling block: old equipment has no sensors, fault samples are scarce, and ROI is hard to quantify — the textile mill's inspection machine tripped on exactly this path.

The fifth layer is platform-based organizational transformation: SANY (Chinese: 三一) partnered with RootCloud (Chinese: 树根互联), Haier incubated COSMOPlat, and Midea (Chinese: 美的) productized its "Meiqing" (Chinese: 美擎) experience for external export, forming a division of labor where "big players build platforms, SMEs board them." On the institutional side, the Implementation Plan for the "AI + Manufacturing" Special Action issued by the Ministry of Industry and Information Technology (MIIT) (Chinese: 工信部) and seven other departments[10-107], combined with the 8-segment, 40-scenario guidance and tiered nurturing, forms a three-in-one promotion framework.

The latest cohort of the Lighthouse network keeps confirming the positive correlation between "AI density" and operating performance: in January 2026 the Global Lighthouse Network added 23 new sites, 16 of them in China; WEF simultaneously launched Lumina, an AI industrial-intelligence platform that aggregates data from the past eight years of the Lighthouse network and over 1,000 transforming factories for benchmarking. WEF's statistics show that 94% of successful transformations result from combining multiple technologies, and lighthouse factories

that integrate technology with talent and sustainability programs outperform industry peers by more than 16% on operating performance[10-143] [third-party verified]. The standout results of the new cohort concentrate in "embedding AI into core operations" and "scaling digital transformation across the network rather than within a single factory." The World Economic Forum and Accenture's *From Potential to Performance: How Leading Organizations Are Making AI Work* draws on hundreds of cases across more than 30 countries and 20-plus industries to distill five factors behind AI at scale: embedding AI in strategic decisions, reshaping how people and AI collaborate, strengthening the data foundation, building a modern technology platform, and practicing responsible AI governance. The Forum simultaneously announced the second cohort of 20 MINDS awardees, in which manufacturing is among the most concentrated sectors and nearly half the names come from China. The quantified results include: Foxconn with BCG scaling an AI agent ecosystem to automate 80% of decision-making processes in global operations, unlocking about $800 million in value; Lenovo using a unified AI agent to coordinate global supply-chain scheduling, lifting logistics accuracy by 30% and providing up to two weeks of early warning on disruptions; Siemens and EthonAI standardizing factory AI visual inspection, saving €30,000-100,000 per inspection station; CATL and Anmaiosheng building hybrid AI systems in data-scarce industrial settings, cutting quality variance by 50% and halving operator workload; and Black Lake Technology raising factory utilization to 83% and cutting energy per unit by 18% through AI scheduling[10-198]. **The report's central proposition is divergence: the gap between companies that can scale AI and those still looking for a method is becoming manufacturing's first dividing line.**

10.9.3 Benchmark Cases

Shenglong Electric: 27 Agents in 14 Days [third-party verified]

The *2026 China Manufacturing AI Scenario Application White Paper*[10-102] documents 167 implementation cases with "verified company identities and quantifiable data." Shenglong Electric (Chinese: 盛隆电气) is the sharpest of them: 27 industrial agents deployed in 14 days, collaboration labor costs down 60%, ROI above 200%. The white paper also offers a sober set of structural data: generative AI accounts for only 4.8% of these cases and AI agents just 3%, while traditional machine

learning (46.7%) and machine vision (20.4%) remain the workhorses — **the existing technology is actually sufficient; the bottleneck is scenario fit and how it is deployed**.

Figure × BMW: Humanoid Robots Enter a Mass-Production Line for the First Time [official claims]

The Figure 02 completed an 11-month deployment at BMW's Spartanburg plant: more than 1,250 hours of cumulative operation, over 90,000 components loaded, and participation in producing more than 30,000 X3s[10-103]; sheet-metal loading completed within an 84-second cycle at 5 mm tolerance, with a positioning success rate above 99% [official claims]. BMW's Munich plant, meanwhile, represents the alternative "digitally native" route: digital twins run through development and production validation, and collaboration with Siemens and NVIDIA has accelerated pneumatic simulation by 30x[10-104] [third-party verified]. Embodied AI has received production-scale data for the first time, and the engineering boundary has been genuinely tested.

CITIC Pacific Special Steel: What AI Looks Like in Process Industries [third-party verified]

In McKinsey's lighthouse-factory cases, CITIC Pacific Special Steel (Chinese: 中信泰富特钢) uses AI to accurately predict and adjust blast-furnace operations in real time, lifting output by 15% and cutting energy consumption by 11%[10-97] [third-party verified]. This is the typical form of AI in process industries: fusing "mechanistic models + data models" to optimize process parameters rather than replace people. The chemical industry concentrates on the same four directions — process optimization, predictive maintenance, safety early warning, and energy optimization — and process departments must lead; IT departments cannot own this.

Baosteel: the rare combination of company-level AI strategy and quantifiable returns. [third-party verified] A TMTPost (Chinese: 钛媒体) review of eight listed Chinese steelmakers' AI investments found most still stuck at demos, pilots, and "storytelling" — and Baoshan Iron & Steel (Baosteel, Chinese: 宝钢股份) the only company combining a company-level AI strategy with quantifiable results: its April 2026 "AI+" theme day disclosed 582 AI scenarios live with cumulative benefits above 270 million yuan, released the AI Scenario Whitepaper (2026 edition) covering 6 business links and 23 scenario categories, and launched the AI digital assistant "Zhibao" (Chinese: 智宝)[10-141]; the annual report shows 347 AI scenarios went live in 2025, and the Baoshan base's "high-end green silicon-steel predictive smart factory"

made the first batch of 15 pioneer-level intelligent factories[10-142]. To judge whether a manufacturer is genuinely AI-native, look at whether strategy level, scenario density, benefit accounting, and organizational mechanisms form one integrated whole — the industry widely publishes use-case counts but rarely discloses benefit data and organizational support. **CATL: putting AI inside core R&D rather than on the periphery [official claims]** — its "augmented intelligence reshaping next-generation lithium battery design" project, led by chief manufacturing officer Ni Jun and Jin Wenjing, won a MINDS award as an "AI-driven industrial transformation global benchmark" at the World Economic Forum's 56th annual meeting. The company says its intelligent cell-design platform has learned from more than 100,000 battery cases, 600TB of test data and a large volume of post-market EV data; it generates design recommendations in seconds and delivers a virtual cell in minutes against user-defined performance targets, with 95% accuracy in performance prediction and a 30% gain in design productivity, marking a shift from trial-and-error experimentation to data-driven forward design[10-201]. **What makes it worth recording is not the flattering numbers but that AI landed in core R&D rather than in inspection or customer service.**

Supcon: a measurable landing sample in process industries [official claims] — at the Huayi Qinzhou chemical materials integration base, the company built a "digital immune system" on its TPT platform, monitoring more than 500 key process indicators around the clock, predicting abnormal trends 2.5 minutes ahead, cutting the standard deviation of hydrogen-sulfide fluctuation by 30% and compressing abnormal-condition handling from hours to minutes; the company says it has deployed over 100,000 control systems in total and assembled a four-in-one capability across data assets, industry knowledge, core algorithms and product platforms[10-202]. **Compared with counting how many agents were released, indicator-level measurable results are closer to the acceptance criteria manufacturing AI should be held to.**

10.9.4 Failure Warnings

Deloitte Survey: 91% of Industrial AI Projects Missed Expectations, and 90% of the Failures Were Not Technical [third-party verified]

Only 9% of China's manufacturing AI projects achieved 80%-100% of expectations[10-100]. The failure attributions are strikingly consistent: requirements get distorted after passing through three layers — decision-makers → IT department →

vendor. One company invested millions in a "knowledge assistant"; three months after launch, daily active users fell to single digits and it was shut down. Frontline workers did not trust a system claiming 99% accuracy and insisted on manual re-inspection. After the vendor delivered, no one maintained the model, and the degraded system was switched off. The survivors share the opposite traits: entry through small scenarios, workers involved in defining requirements, and data governance up front.

The Full Lesson of the Fabric Inspection Machine [third-party verified]

Back to the textile mill at the start. Behind the 3.7 million yuan investment and the 15% misjudgment rate[10-101] are three things that were not done right: insufficient scenario diversity and standardization (the same fabric's reflection characteristics vary widely between batches); know-how divorced from samples (the experience in the veteran workers' heads never became the machine's training data); and single-point equipment retrofits that cannot solve systemic problems (the machine replaced human eyes, but no one is backing up the machine).

Jumping In Blind: A Missing Data Foundation [third-party verified]

One manufacturer skipped pilots and data preparation and went straight to full-process AI quality inspection; insufficient training data meant accuracy failed to meet standards, the production line could not run, and the project failed and had to be redone. About 60% of enterprises ignore the principle that "data and business preparation come before technology." The common thread in these failure paths is not weak algorithms but organization and data infrastructure falling behind.

Murata's "data-trap" survey. [third-party / corporate survey] Murata Manufacturing's (Chinese: 村田制作所) questionnaire survey finds more than 38% of factories are implementing or planning smart-factory initiatives, with the share still rising — but smart-factory projects commonly fall into data traps: incomplete collection, uneven quality, and a focus on local equipment rather than end-to-end process data, so heavy investment fails to deliver efficiency[10-144]. The value ceiling of a smart factory is set by data governance, not by the quantity of equipment and algorithms — "intelligentization for its own sake" is becoming manufacturing's new inventory. **The 68% stuck at POC: failure modes now repeatedly verified.** The industrial data-infrastructure vendor HiveMQ identifies three failure modes that "kill industrial AI," the first being a data pipeline that cannot migrate — a custom data path built for a single use case in a single plant and started over from scratch at the second plant. The countermeasure is to design for portability before the first pilot: invest in a

shared data backbone any use case can subscribe to, and standardize naming conventions, metadata and data models in advance so the second site does not have to rebuild[10-199]. Another analysis firm states the mechanism of "pilot success, production failure" even more plainly: the machine learned the patterns, but the organization never built the system for acting on them — it lacks decision infrastructure. A 2026 Kaufman Rossin survey found 73% of mid-sized manufacturers still stuck in the pilot stage, with legacy ERP systems and data silos the main obstacles (cited from MarketScale, July 2026). The illustration given is a mid-sized industrial distributor with 480 employees and $90 million in revenue: an eight-week pilot predicted supplier delays 72 hours ahead with over 80% accuracy, yet after the pilot nobody adjusted procurement based on those predictions[10-200]. **Both sources point to the same conclusion: the problem is not on the model side but on the "who does what with the model's conclusion" side — decision ownership, human-in-the-loop governance and process redesign are the bridge from pilot to production.**

10.9.5 Organizational Patterns and Consulting Takeaways

If you go to consult a manufacturing company on AI transformation, the first thing is to help it separate two kinds of problems: **"physical cycle-time problems" (AI cannot help — don't waste money) and "decision and information problems" (AI can help — worth investing)**. In McKinsey's lighthouse analysis, generative AI's fastest gains appear precisely in the process and knowledge scenarios outside the workshop — ACG Capsules' SOP assistant was used by nearly three-quarters of operators within five weeks[10-97]. Manufacturing AI's ROI concentrates in the decision layer and in the "documentation and administrative layer surrounding production" (SOP assistants, reports, knowledge Q&A, scheduling), not in the physical layer itself.

On the deployment sequence: single point first, platform second, organization last — start with high-frequency single points like quality inspection and scheduling to validate ROI, then build the data platform and model-asset management, and only then touch the organization (Chief AI Officer, AI Center of Excellence, business-unit AI specialists). McKinsey offers three levers for scaling: packaging use cases as "assets," low-code platform acceleration, and phased introduction — AI assists decisions first, and automation follows once confidence thresholds are exceeded.

The data foundation determines AI's ceiling: defect-sample generation, OT/IT integration, and the fusion of mechanistic and data models are the three engineering prerequisites. Predictive maintenance — the scenario with the clearest ROI — is exactly where "data-infrastructure debt" is most exposed.

Finally, the choice of organizational path. Manufacturing companies incubating AI platforms have three routes: internal incubation + external independent operation (SANY/RootCloud); validation in the parent factory + platform company exporting outward (Haier COSMOPlat, Midea Meiqing); and the "research institute + industry company" dual entity (Digital Building Materials Research Institute/"Xiaomiao"). What they share is letting AI capability break free of the parent organization's inertia and compete as an independent entity. And on any route, business-led rather than IT-led is the prerequisite — the chemical industry wrote this into its own practice, and academia summarizes it as the stage transition of "cognitive awakening → strategic decision → organizational change → technology implementation → capability consolidation." Manufacturing's AI-native transformation has never been a technology-procurement problem; it is an organizational learning process.

The main constraint on manufacturing AI is not whether to invest but how capital-expenditure cadence matches payback cycles. Morgan Stanley argues that Chinese manufacturing is moving from "Industry 4.0" into "Industry 5.0," with the focus shifting to AI, robotics, autonomous industrial technology, and ecosystem exports rather than automation and informatization alone; its estimate is that global industrial capital expenditure will total about $50 trillion between 2026 and 2035, of which roughly $12 trillion is new "Industry 5.0" investment[10-232]. **Placed in an organizational context, the implication is this: when the industry enters a new investment cycle built around AI and autonomous industrial technology, the decision chain, engineering workforce structure, and supply-chain coordination methods must all be reset on the premise that "AI participates in decisions," rather than layering tools onto old processes.**

At the regional level, the approach takes the form of "platform first, scenarios after." Wuxi High-tech District (Chinese: 无锡高新区) proposed "All In AI" in 2026, paired it with two three-year action plans for industry development and "AI + manufacturing," and broke ground on the country's first computing-equipment industrial park. Its key hub, the "Xishu Workshop," is positioned as an on-demand online "solution supermarket"; by July 2026 it had organized more than 310 large industrial enterprises to complete online AI self-diagnosis, 76 local firms entered

Jiangsu's 2026 list of advanced smart factories, and 19 service providers entered the provincial list of "AI + manufacturing" diagnostic providers. One judgment from the piece is worth recording: a watershed appeared in the industry after DeepSeek — **training large models was the main theme before, and using large models became the trend after** — which is what gives "AI+" room for city-by-city adaptation[10-233].

But there is still a hard gap between "a pilot has been started" and "the conditions for scale exist." Deloitte's *2025 Future of Manufacturing* found 87% of surveyed manufacturers had launched at least one generative AI pilot, and predicted that 25% of firms already using generative AI would launch agentic AI pilots in 2025, rising to 50% by 2027. Yet Deloitte's *2026 State of Enterprise AI* reveals the contrast: nearly three-quarters of enterprises plan to deploy agentic AI within two years, while only one in five considers itself ready[10-234]. The pattern experts describe repeats: a company launches a pilot, executives announce a grand AI strategy, and then integration difficulties, poor data quality, and delayed returns follow. **The question is no longer whether to use AI but whether it can move from experiment to scaled deployment — and Gartner predicts more than 40% of agentic AI projects will be cancelled by the end of 2027, precisely because of unclear business value, rising costs, and implementation challenges. Manufacturing's authoritative voices are now defining "AI transformation" directly as "organizational restructuring."** McKinsey's *State of Organizations 2026*, based on a survey of over 10,000 senior executives across 15 countries and 16 industries, names three forces rewriting the future of organizations — the technology wave (AI moving from an assistant tool to "taking over processes"), persistent uncertainty, and changes in "people" (talent logic shifting from "looking at the job" to "looking at capability") — and makes its first action theme "building an AI-powered organization"; its core judgment is that few companies truly turn AI into performance, and the problem is not that the technology is weak but that many treat AI as a "tool upgrade," ignoring that it is fundamentally an "organizational restructuring" that requires reopening cross-departmental processes, rewriting how work is done, and even remaking the performance logic from the ground up; the report foresees leaders evolving into "agentic enterprises," where the shadow of a "team" already appears when multiple agents collaborate[10-272]. **The workforce-side lesson comes from the Global Lighthouse Network**: WEF distills three things — using AI to build people-centered workforce planning systems, systematic digital and AI skills training,

and education-partner talent onboarding/training programs — and cites Haier's Chongqing plant using an AI-driven key-talent identification and career-development platform to help employees plan their growth[10-273]. **International echoes of the Chinese sample appear at the same time**: Lenovo's case of "building a carbon-silicon fused AI-native organization" was selected for the 2026 Enterprise Management Best Practices list and won "Annual Top Ten Best Practices," with organizers noting it "redefined the organizational paradigm of the AI era and tested AI value by business results," and the report summarizing the industry's growth focus shifting from "+AI" (adding AI to old processes) to "AI+" (reshaping the organization with AI)[10-274]. **The demand-side judgment converges**: PwC summarizes the current shift in organizational form as "the rise of the generalist" — the old model of deeper functions, higher layers, and narrower roles is turning toward broader, outcome-oriented jobs, warning that under the agentic AI shock companies easily make the wrong organizational design (for example, merely cutting jobs)[10-275]; iResearch's *2026 China Industrial AI Agent Development Report* sets the direction as moving from "general-purpose agents" to "specialized-scenario agents," with the core selection criterion shifting from model capability to whether it can close the loop on delivering business results[10-276]. **Frontline consulting retrospectives move the cause of failure from technology back to organization**: one manufacturing consultancy's analysis finds the most common causes of AI project failure are organizational — lack of executive sponsorship, frontline resistance, an unclear business case or no clear ROI, and failure to integrate the solution into daily operations — citing data that poorly executed AI projects run on average 15–20% over budget and 6–9 months late[10-277].

The organizational variable in manufacturing keeps pointing to the same place. Industry surveys continue to show manufacturers extending AI use cases from point scenarios such as quality inspection and scheduling into more complete operational processes[10-304]. But smart-factory programs usually stall on something other than technology selection: one industry analysis treats shop-floor resistance as a manageable change variable rather than an execution fault — inadequate workforce readiness and change management is the main reason smart factories stop at the demonstration line[10-305]. **This matches Chapters 5 and 6 exactly: for AI projects in manufacturing, the real bottleneck is usually off-screen.**

Manufacturing's "AI-native" has entered the language of chief executives. At the 26th China International Industry Fair in September 2026, Haier chairman and CEO Zhou Yunjie summarized the shift in what advanced manufacturing means with three lines: from automation to AI-ification, from pursuing certainty of scale to absorbing uncertainty of demand, and from point efficiency to system resilience; the competitive focus moves from "what the machine can do" to "how the enterprise uses intelligent technology to keep creating user value." At the organizational level he used the phrase "restructure enterprise processes and organizational capability the AI-native way," adding that "technology upgrading is not simply stacking tools, but a systemic reconstruction of the mode of production, the organizational model and the logic of value creation"[10-319]. **This is corporate self-description rather than third-party verification, but it marks one thing: the public language of China's leading manufacturers has moved from "how many scenarios have we deployed" to "how do we change the organization."** Read against the paths in 10.9.2, the landing point of that sentence is not the production line but processes and performance reviews — scenario counts are no longer a boast.

10.10 Energy & Utilities

10.10.1 Industry Profile and Bottleneck Triage

In 2025, Duke Energy's AI grid prevented about 1.2 million outages across the Carolinas — resolving them before they ever reached customers, saving roughly 3 million hours of outage time in total[10-115] [third-party verified]. The approach is not flashy: AI prediction models identify equipment failure risks and vegetation hazards, rank risk priorities by combining weather and asset condition, and schedule trimming and maintenance in advance. This is a legacy American utility that started in 2017 with a single-point use case detecting electricity theft and arrived at 2025 with 50-plus generative AI use cases in flight[10-116] [third-party verified]. Its path is more worth studying than any "year one of energy AI" slogan.

Energy and utilities have the highest physical-bottleneck share of any industry in this book: an information:physical ratio of roughly 20-30:70-80. Power flows on the grid, pressure in pipelines, and turbine speeds are all millisecond-level physical realities — no matter how clever the algorithm, it cannot change Joule's law. The global energy AI market surpassed US$40 billion in 2025, and the power-industry AI

agent market exceeded 40 billion yuan [third-party verified]; yet value has been slow to arrive — utilities have invested over US$10 billion in AI over the past five years, and most projects have not moved beyond the pilot stage [third-party verified].

Behind the gap are four core contradictions. Physical safety constraints have top priority: dispatch errors can trigger large-scale blackouts or even human casualties; the US NERC CIP regulatory framework has no clear definition for AI models; and the nuclear industry requires AI to enter only "human-machine collaboration" scenarios, never autonomous control. Heavy assets and long cycles: SCADA, mainframes, and other legacy systems 20-30 years old cannot communicate with modern AI platforms, and companies spend 40% of their AI budgets just making old systems "talk"[10-117] [third-party verified]. Data fragmentation: data is scattered across dozens of isolated systems, and models are trained on incomplete, biased datasets[10-120] [third-party verified]. Dual regulatory and performance constraints: central state-owned enterprises (central SOEs) are assessed on KPIs, and grid operators must guarantee supply — leaving far less room for error than the internet industry.

10.10.2 Transformation Paths and Typical Practices

Grid AI's path is "industry LLMs become the new foundation." State Grid (Chinese: 国家电网) released "Guangming" (Chinese: 光明), China's first 100-billion-parameter multimodal power LLM, in December 2024[10-110], and its "6541" master plan (six application domains, five intelligent systems, four-in-one foundation) in May 2025; its intelligent customer service now auto-responds to more than 90% of work orders, with 270 million cumulative interactions [official claims]. China Southern Power Grid (Chinese: 南方电网) took the domestic-compute route: "Dawate Yudian" (Chinese: 大瓦特·驭电), trained on a Huawei Ascend cluster with 13 billion parameters, was selected among the "top-ten national heavyweights" of central SOEs, and platform model calls surpassed 10 billion in December 2025[10-112] [official claims]. Both grids use a "headquarters LLM + localized small models" architecture: a dispatch robot in Xuancheng, Anhui, compressed dispatch-order drafting from 3 hours to 30 minutes, and converter-transformer fault diagnosis in Liaocheng, Shandong, went from a week to milliseconds [third-party verified].

Oil and gas LLMs are moving from "single-well intelligence" to an "industry brain." CNPC's (Chinese: 中国石油) Kunlun LLM (Chinese: 昆仑大模型) released its 300-billion-parameter version (MoE architecture) in May 2025, covering 26 business lines and 119 business domains[10-113] [official claims]; Sinopec (Chinese: 中石化) uses the "Great Wall

LLM" (Chinese: 长城大模型) as the group's foundation. Data has been elevated to equal status with models: CNPC has built a 550 TB three-tier data management system, and "data is the blood of model training" has become industry consensus [third-party verified].

New-energy operations and maintenance are shifting from "veteran experience" to "precision diagnostics." In Q1 2025, wind and solar installed capacity reached 1.482 billion kW, surpassing thermal power for the first time, and the surge in capacity pushed O&M toward AI: Envision (Chinese: 远景) trains agents on millions of real operation-and-inspection data points [third-party verified]; Goldwind (Chinese: 金风) does predictive maintenance with digital twins + IoT [third-party verified]; Shenzhen Energy (Chinese: 深圳能源), with Huawei Cloud, released a power-forecasting system that reduces wind and solar curtailment [official claims]. Industry-wide fault-identification accuracy has risen above 90% [third-party verified].

Nuclear power and virtual power plants are the two endpoints of most conservative and most cutting-edge. In nuclear, China National Nuclear Power's (Chinese: 中国核电) "Hezhi AI Portal" (Chinese: 核智 AI 门户) has integrated DeepSeek, and CGN (Chinese: 中广核) is building a full-lifecycle nuclear intelligence hub on 18 core datasets — but applications are strictly limited to "human-machine collaboration" scenarios such as decision support and procedure interpretation [third-party verified]. In virtual power plants, the AI dispatch at the Dongguan energy-storage station completes 10 MW power allocation within 0.5 seconds [third-party verified]; China's 2025 target for virtual power plant regulation capacity is 20 million kW [third-party verified].

Computing–electricity synergy has moved from an industry topic to national strategy: in 2026 it appeared for the first time in the Government Work Report and entered the 15th Five-Year Plan outline; the four-department Action Plan for Two-Way Empowerment of AI and Energy (Chinese: 《人工智能与能源双向赋能行动方案》), issued by the NDRC and the National Energy Administration among others, makes it a key task and encourages new computing facilities to sign multi-year green-power purchase contracts with renewable-energy companies[10-145]. On the ground, China Southern Power Grid has built the country's first electricity–carbon–computing coordination operating system and is running cross-regional dispatch pilots in Guangdong, Guizhou, and Jiangsu; during peak summer, Shanghai organized 16 data centers to complete the country's first full-mode, scaled computing–electricity synergy

test. AI computing power is both a new load on the grid and, aggregated through virtual power plants, a high-quality flexible resource — for the first time, the demand side and the supply side of the same grid can trade places.

The maturity divergence inside energy is itself a baseline that must be measured first. RSM US, reviewing research and company disclosures, finds that confirmed AI deployment rates reach 90% in electric utilities, clearly higher than in most oil and gas sub-sectors — the grid side entered scale earlier thanks to its data foundation and regulatory pressure, while the lag in oil and gas risks missing efficiency windows in upstream exploration, refining, and safety scenarios[10-169] [third-party verified]. **For consultants and vendors, the degree of divergence within an industry is itself a baseline that must be measured before any deployment strategy is set.**

10.10.3 Benchmark Cases

Changqing Oilfield × Huawei: A Full-Stack Autonomous Smart Oilfield [official claims]

Changqing Oilfield (Chinese: 长庆油田), China's largest onshore oil and gas field (annual oil and gas equivalent output above 60 million tonnes, managing 126,000 wells), partnered with Huawei and Kunlun Digital Intelligence (Chinese: 昆仑数智) to build a three-tier architecture of "cloud centralized training — regional inference management — edge real-time inference" on a fully self-developed technology stack of "Kunpeng + Ascend + Galaxy Kylin." Its "special-operation hazard intelligent identification project" collected 2 million operation images and 150,000 hours of video, built a knowledge base of 12,000 rules, and deployed 20 high-precision models, achieving 94.1% hazard-identification accuracy (18.7 percentage points above traditional methods), edge-side inference latency under 800 milliseconds, a 70% reduction in manual supervision intervention for high-risk operations, and 18% lower overall operations and maintenance costs[10-114]; in reservoir-development scenarios, detection accuracy rose from 78% to 92%, and unplanned equipment downtime fell by 50% [official claims]. It is a complete sample of the full-stack autonomous route.

Duke Energy: Predictive Maintenance Proven at Scale on the Distribution Grid [third-party verified]

Back to the story at the start. Even more valuable is the organizational method: it began in 2017 with a single-point use case detecting electricity theft, established governance guardrails in 2024, and reached 50-plus generative AI use cases in flight in 2025. The CIO's three principles — Always on (reliability first), Data before dazzle (don't bolt AI onto bad data), and Human in the loop (AI augments people rather than replaces them) — are the classic articulation of utility AI governance[10-116] [third-party verified].

The Kunlun LLM: An Organizational Sample of a Central-SOE "Industry Brain" [official claims]

The Kunlun LLM was launched by the group's Party leadership in January 2024, became the first energy-and-chemical-industry LLM to pass national filing in August 2024, and grew to 300 billion parameters in May 2025[10-113] [official claims]. It represents a collaboration model of "central-SOE headquarters coordination + ecosystem partners co-building," with the goal of upgrading from "model capability" to an "industry brain" reusable across the whole sector [third-party verified].

China Southern Power Grid's "DaWate·Yunrui": an agent sample for distribution-network planning. [official claims + third-party verified] As reported by People's Daily (Chinese: 人民日报), CSG's distribution-network planning agent "DaWate·Yunrui" (Chinese: 大瓦特·云睿) generates a distribution-network plan serving over 10,000 residents in 10 minutes from load, solar, and storage data, and was selected among the top ten "treasures of the hall" at WAIC 2026 from more than 1,100 companies and 3,000+ exhibits; it has been fully deployed across Yunnan Power Grid, completing over 10,000 grid risk diagnoses and generating more than 8,000 plans, with source-load forecasting and problem diagnosis above 90% accuracy and plan usability above 95%[10-146]. Planning reports that once took days are compressed to ten minutes — high-skill roles such as grid planning and dispatch are having their working rhythm rewritten by agents.

10.10.4 Failure Warnings

74% of Pilots Never Leave a Single Region [third-party verified]

Prudent Consulting research shows that 74% of AI pilots in the utility industry never reach production in more than one region[10-117]. The six root causes are almost all organizational: legacy-system integration barriers (40% of budgets spent on connecting old systems), data architecture not built for AI, no AI lifecycle management

(models abandoned after 12-18 months without retraining as accuracy decays), skill gaps and organizational misalignment, missing governance, and improper ROI measurement [third-party verified].

70% of Leaders Are Dissatisfied with AI Progress [third-party verified]

A BCG 2024 survey found nearly 60% of energy company leaders expected AI results within a year, but about 70% are dissatisfied with progress[10-118] — the gap between expectation and reality constitutes the energy industry's "AI anxiety" [third-party verified]. The industry also widely suffers from "build but don't use": after projects are completed, there are no operations people to run them, and models become ornaments [third-party verified]. The IEA notes that the energy industry overall underutilizes AI, with data availability and digital skills the main barriers[10-119] [third-party verified].

10.10.5 Organizational Patterns and Consulting Takeaways

First, draw the physical safety boundary for AI. Energy is an industry where "errors are irreversible": AI's value concentrates in the decision and information layers — inspection recognition, load forecasting, dispatch assistance, knowledge retrieval — and wherever human life and grid safety are involved, human accountability must be preserved. The early lesson from the US GridFWD conference is that "capital is too precious and the risk of getting it wrong too great" — build the governance model first, then talk about use cases[10-120] [third-party verified]. The first consulting move is to help the enterprise clarify which scenarios AI may only "recommend" and which it may "execute."

Single point first, then systems, then organization. Duke started with one theft-detection use case in 2017, built governance guardrails in 2024, and only scaled in 2025[10-116]; State Grid Hangzhou's (Chinese: 国网杭州) experience is to prioritize scenarios that are "high-frequency, high-value, low-risk" and to establish cross-departmental AI teams[10-117] [third-party verified]. "Slow first, fast later — earn the right to move quickly" is closer to the truth than rushing into big-bang launches [third-party verified].

The data foundation and centralized control centers are dual prerequisites. Prudent lists "data architecture not built for AI" among the root causes of failure [third-party verified]; Changqing invested 2 million images + 150,000 hours

of video + a 12,000-rule knowledge base[10-114] [official claims]. Central SOEs generally adopt a "group-level platform + edge inference" control architecture, treating data governance and compute infrastructure as infrastructure rather than projects.

The particularity of organizational change in central and state-owned enterprises: KPIs and error tolerance. State Grid is moving from the "6541 plan" to a special action of "two years to consolidate the foundation, three years to drive improvement"[10-109] [official claims], and China Southern Power Grid deploys 29 key measures through annual work plans [third-party verified] — AI is being upgraded from project-based to routinized mechanisms through documents, KPIs, and dedicated institutions. But KPI-driven change has its costs: the "build but don't use" phenomenon is prominent. The consulting takeaway is to design a dual-track mechanism of "pilot-stage error tolerance + scale-stage KPI assessment" so AI does not become political achievements on paper.

Upgrade AI from a tool to strategy and business model. BCG argues for moving from "piloting AI" to an "AI-first operating model": embed AI into core business processes rather than edge applications, form fused teams of data scientists and domain experts, and co-develop with technology companies rather than buying[10-118] [third-party verified]. Guidehouse goes further: AI will push utilities from "operational optimization" toward "business model reconstruction" — making virtual power plants and dynamic pricing possible[10-119] [third-party verified]. And the IEA's proposition that "no AI without energy, no energy without AI" [third-party verified] makes energy the only industry where AI's demand creator and user are one — the biggest strategic variable for energy's AI-native organizations.

Governance is not a compliance burden but the admission condition for whether innovation is allowed to reach critical systems. Utility Analytics Institute argues for building AI governance into the 2026 strategy rather than retrofitting it after something goes wrong[10-170]: for an industry where a single accident is a social event, governance determines whether AI can touch critical systems and real-time decisions. The implicit organizational requirement is a cross-functional governance mechanism (business + IT + legal + data + security) with clear accountability, so that innovation speed and risk control can be managed at the same time, avoiding both extremes — freezing everything over risk, or letting pilots sprawl out of control.

The control room is where energy AI is first allowed in. Deloitte's *2026 Power and Utilities Industry Outlook* projects that nearly 40% of utility control rooms will use AI by 2027. It lists three organizational changes: in grid operations, AI augments traditional predictive maintenance to prioritize work, reduce failures, raise crew productivity, and restore power faster; for frontline staff, generative AI assistants trained on manuals and incident logs guide technicians in real time and improve first-time fix rates; and at the grid edge, embedded intelligence controls events, voltage, and distributed energy in milliseconds, letting feeders and microgrids self-adjust in real time under operator supervision[10-235]. The report also makes clear that utilities will expand control-room AI analytics and generative AI assistants more widely in 2026 while institutionalizing supervision frameworks — **human oversight remains central.**

On the storage side, "remote operations replacing on-site inspection" has already produced measured results. China's first AI data-analysis platform for new-type energy storage entered operation, and after a year of trial running reported two figures: equipment failure rates at eight power stations fell 34%, and renewable energy absorbed rose about 30%; the platform relies on autonomous learning and large-scale data analysis to find hidden equipment defects remotely and in real time[10-236]. **Its value for organizational research lies in the job structure: O&M staff shift from blanket inspection to handling the anomalies flagged by the platform and adjusting strategy — the value of the role moves from routine inspection to anomaly determination, maintenance decisions, and revenue-strategy optimization.**

Large state-owned energy enterprises advance more in the sequence of "document — task force — scenario." China Huadian (Chinese: 中国华电)'s timeline is clear: November 2025, release of the "Huadian Zhi" industry large model; January 2026, issuance of an AI navigation action plan for power safety production with an explicit timetable and roadmap; May 2026, a progress meeting; July 2026, release of the "Huadian Zhi · Yuneng" power safety production model[10-237]. **The timeline itself is a record of how state-owned energy companies institutionalize AI: establish a general industry model first, then set the timetable through an action plan and navigation mechanism, and finally land on dedicated models for specific scenarios — not project-style pilots, but implementation in the order of document, task force, scenario.**

Energy's AI variable has overflowed from an "internal efficiency problem" into "a restructuring of capital and regulation." The most emblematic deal of 2026 is NextEra Energy's proposed ~$67 billion all-stock acquisition of Dominion Energy, which after merging would serve about 10 million utility customer accounts across Florida, Virginia, and the Carolinas — its strategic basis being to capture the power demand of Big Tech data centers (Virginia hosts the world's largest data-center cluster, and Dominion is the local leader powering hundreds of them), with success depending on persuading state regulators[10-278]. **Long-term supply contracts have turned "AI electricity demand" into concrete asset transactions**: Microsoft signed a 20-year, $16 billion power-purchase agreement with Constellation, taking the entire 835MW capacity of the restarted Three Mile Island Unit 1; Google signed the US's first corporate SMR agreement with Kairos Power (500MW); Amazon invested more than $20 billion to convert Susquehanna — against a backdrop in which global data-center electricity use is projected to rise from 460 TWh in 2024 to 1,300 TWh in 2035[10-279]. Meta joined the queue in June 2026, signing a 20-year deal with Constellation to buy 1.1GW of nuclear power from its Clinton Clean Energy Center in Illinois; Deloitte's analysis holds that nuclear can meet at most about 10% of data-center power demand by 2035[10-280]. **But there is still a considerable distance between "announced megawatts" and "deliverable megawatts"**: the *Bulletin of the Atomic Scientists* notes critically that Big Tech's nuclear announcements are "heavy on self-promotion," and that their nuclear commitments amount to "less than one percent" of annual data-center spending (Amazon and Google's 2026 data-center spending could reach $200 billion and $185 billion respectively); as of July 2026, the world had 11,826 data centers (4,467 in the US)[10-281]. **On the grid side, however, AI is already in daily operations**: Iberdrola uses AI to predict the failure probability of line and transformer assets and to analyze usage patterns to forecast where and when demand will be higher; its US subsidiary Avangrid announced in September 2026 an expansion of AI across the business, covering drone grid inspection, customer-sentiment analysis, and accelerated grid planning, and co-developed a generative AI product, "First Time Right," with Amazon Bedrock to help technicians locate and resolve wind-farm problems[10-282]. **Energy is the only industry where "AI is both the tool and the biggest customer" — AI demand is supplied by it and, in turn, reshapes its investment portfolio and organizational structure, which is precisely what makes its organizational change distinctive.**

The energy sector's samples explain why the position of the human-machine division matters. The World Economic Forum's June 2026 cohort of "AI application stars" comprises 26 organizations, one of the energy representatives being Occidental — using AI to give geologists and engineers faster, more consistent subsurface images before drilling begins, reducing costly mistakes and improving drilling decisions; AI works on pre-drilling judgment preparation and the output still goes to human experts to decide[10-306]. Industry commentary, meanwhile, emphasizes operations over pilots: service providers and industry media agree that AI pilots have proven effective and the obstacle is no longer the model but operating discipline — trials stop halfway because nobody owns turning them into routine process[10-307].

Grid AI is turning "emergency repair" into "prediction." The NextGrid Alliance run by National Grid Partners already involves 135 utilities and more than 500 senior professionals across 25 countries. National Grid's asset-strategy team uses Monte Carlo-style simulation to forecast which distribution circuits will fall into the worst reliability band by year end; Massachusetts penalizes circuits that come last two years running, so getting the list weeks early means upgrades and vegetation clearance can be scheduled in advance instead of reacting after outages accumulate. Southern California Edison is building a grid digital twin for planners to simulate operating conditions, and its team built its own vision model on the YOLO framework to audit and classify switches on utility poles from imagery; SCE spends roughly $500–700 million a year on tree work and vegetation management and is working with satellite-data firms on continuous monitoring[10-320]. **The value of this case is that three links are connected — regulatory metric, forecast target, work schedule: AI is not there to see, but to turn a penalized metric into a list that can be acted on early.**

On the Chinese side, "hub first" proves to be a workable path in energy. China Southern Power Grid began building its dispatch-cloud platform with Alibaba Cloud in 2018, and AI applications developed on it raised the system-wide load-forecast accuracy at the national dispatch center to 97.63%. That number matters because forecast accuracy directly determines reserve capacity and spot-market strategy — a one-point improvement corresponds to real fuel and power-purchase costs. The organizational path is equally clear: start from the dispatch center, a strong central scenario, until the whole grid accepts one definition and one data standard, then spread to distribution and planning; starting from scattered scenarios instead usually fails to aggregate because definitions do not match[10-321]. **This is the same**

sequence as the "point, system, organization" progression in 10.10.2: in energy, data standards can only be set by the hub, not assembled from scenarios.

Afterword: A Living Book

Having finished the first edition, what I most want to talk about is not the content of this book — it is the book itself.

It came from an automated content pipeline: a system that scans the global information landscape every day, a body of knowledge entries that have been refined again and again, three rounds of targeted deep research, and a weekly automated merge-and-release cycle. From the very first edition, this book was never "finished" — it is **alive**.

That is itself a miniature of the AI-native organization: **delegate repetitive work to systems, keep judgment for humans, and make knowledge an asset that keeps growing.** The book describes how other organizations have done this — and the way this book produces itself is the same principle in practice.

On Limitations

The source material of this book has clear boundaries, and I must state them honestly:

- **Industry boundary**: In the first edition, the vast majority of cases came from information-intensive industries (software, content, finance, consulting), and evidence from physical-world industries (manufacturing lines, clinical medicine, logistics) was scarce. Chapter 10, the industry guide, has systematically closed that gap — manufacturing, healthcare, logistics, energy, and other physical-world industries now have systematic cases and data. But a real boundary remains: the ten industries are covered with unequal depth (information-intensive industries are thicker), and the industry material comes mainly from public reporting, so first-hand operational detail is inherently limited. The sample-bias critique applied to the Tencent Research Institute report in Chapter 3 still holds — extrapolating "the patterns of information-intensive industries" into "universal organizational laws" is dangerous.
- **Time boundary**: AI data goes stale within months. Each data point in this book is timestamped (most as of August 2026); always refer to the latest version.

- **Survivorship bias**: The organizations in our case studies are publicly disclosed transformation samples. Companies that failed quietly will never appear in a book — Chapter 9's failure cases are a limited compensation for this bias.

How to Contribute

This book is free and open. Any reading or sharing is welcome. If you find errors, omissions, or cases worth including:

- Open an issue at the GitHub repository: github.com/Jweokk/ai-native-organization-book (https://github.com/Jweokk/ai-native-organization-book)
- Or write to weokk2025@gmail.com

The value of knowledge lies in its flow, not in hoarding it. This book came from flow — and we hope it keeps flowing.

Appendix A: Case Index and Sources

This appendix lists the original sources for every data point, case, and claim in this book. Attribution convention: company official statements are marked as **official claims**; third-party sources such as media, analysts, and regulatory filings are marked as **third-party verified**. All data is timestamped as of August 2026.

Numbering system: Superscript [numbers] in the body text (e.g., [10-25]) are direct citations — click to jump to the corresponding entry in this appendix. Entries are grouped by source theme ([1-xx] reports & data, [7-xx] international cases, [8-xx] methodology & failure cases, [10-xx] industry guide); any chapter may cite any group. Entries without a superscript in the body are further reading and verification sources on the same topic.

- [7-80] a16z podcast, "Playbook for Rebuilding a Company Around AI" (interview with Kavak founder Ali Massa; Chinese compilation via the Denny newsletter): one dedicated agent per customer, 96% of customer interactions and 95% of transactions handled by AI, 15 roles' capabilities merged into a single sales agent, evals as the brake: https://mp.weixin.qq.com/s?__biz=MzA3MDQyNDUzMA==&mid=2649928659&idx=1&sn=48f40bdd248d45a838c1684832a
- [7-81] International Finance News (国际金融报): "Alibaba Cloud Diangjin builds financial agents that do real work" (CITIC Securities' "one digital employee per role, one assistant per person" as a post-level configuration model): https://www.ifnews.com/news.html?aid=843224
- [7-82] China Business Journal (reposted by Eastmoney): "Banks' AI posture shifts: agent deployment accelerates" (WeBank's 80-plus digital employees; an R&D digital employee cutting security work-order launch time from two weeks to 30 minutes): https://wap.eastmoney.com/a/202608293858898326.html
- [7-83] People's Daily Finance: "Insurance accelerates its embrace of AI: China Life has built more than 500 agents covering underwriting, claims, and agent enablement": http://finance.people.com.cn/n1/2026/0828/c1004-40788240.html
- [7-84] TMTPost: "From super-individuals to a super-organization: the AI-Native Organization forum at the 2026 Yunqi Conference" (Alibaba CPO Jiang Fang: "a collection of super-individuals does not necessarily become a super-organization"; the QoderWork team: five people, seven days; three starting principles — leaders must get in the water first, pilot in a special zone, redesign the workflow rather than graft on tools; more than 600 internal digital

employees at Alibaba Cloud, a ~2,500-person team moving to three tiers of business units, executive digital twin "Patrick"; the roundtable's six-word summary "emerge, select, replicate"): https://www.tmtpost.com/8151919.html

- [7-85] NetEase Zhigi: "An interview with a company where nearly 100% of employees use an AI agent — every pitfall it hit" ("installation rate looks great, usage rate looks thin"; 30–40% of skills reinvented across teams; built a data-access layer and a middle platform of atomic skills; three-level evolution LV1 individual efficiency → LV2 business efficiency → LV3 organizational reshaping; "don't treat the agent as a tool; manage it as an employee"): https://zhiqi.163.com/cms/YyCoNKWQ.html
- [7-86] TMTPost ("Yunqi Strategy Reference"): "Alibaba Cloud CIO Jiang Linquan's 'self-revolution'" (28 categories of digital employees over three years, "equivalent to extending the business teams 2,000 headcount" for an investment far less than those headcounts' annual salaries; the website AI assistant cutting five-hour inquiries to 10-second responses; phone QA from 2% sampling to full-volume inspection; four months after opening up, general-agent call volume grew roughly 1,000x): https://www.tmtpost.com/8141973.html
- [7-87] InfoQ: "64 PRs in a week and a half: after Calendly put agents into the whole R&D flow, the bottleneck shifted to judgment" (a durable closed loop — requirements in Jira, review history in GitHub, verification in CI, behavioral constraints in repository instructions; the IAM team generated 64 PRs in roughly a week and a half, 37 merged and 27 in review, covering about 30% of the work to decouple the IAM data model from the monolith; agents run under a dedicated Service Identity and still pass through two human review gates; an internal tool let a designer and a PM deliver their first PRs; the bottleneck moved from writing code to alignment to judgment — "handing a vague ticket to a very fast agent does not get you a correct result faster, only a wrong result faster"; cites CodeRabbit research that AI-assisted PRs surface about 1.7x more issues than fully human PRs and show roughly 75% higher odds of logic errors): https://www.infoq.cn/article/0yv69MyNwHiwY3IZXPQt
- [7-88] SmartHR Tech Blog: "AI-native development" (the goal is a development system optimal for AI rather than merely putting AI tools into engineers' hands; the parts formerly passed on orally by senior engineers — how specs are written, how reviews are read, how verification is done — are turned into processes an agent can execute): https://tech.smarthr.jp/entry/2026/06/04/094730

- [7-89] SmartHR Tech Blog: "The road to introducing AI agents across a team" (spread starts from one experimental squad and scales layer by layer as others see that it really is faster and easier, then reproduce it, until teams share one environment): https://tech.smarthr.jp/entry/2026/04/28/165243
- [7-90] LINE Yahoo Tech Blog: "Automating PR review preparation with Claude Code × MCP" (an agent first gathers the scattered context — intent of the change, linked issues, relevant history — into review material, then humans judge; what is saved is preparation time rather than review time, about six hours per week per team; review authority is untouched): https://techblog.lycorp.co.jp/ja/20260122a
- [7-91] Plaid Tech Blog: "A setup for running Claude Code as a team that survives a 4x increase in PRs" (all agent configuration is committed to the repository alongside human documentation; Permission and Hooks enforce mechanically — reads allowed by default, `git push` asks every time, `rm -rf` refused, format and type checks after edits, protected-branch pushes blocked and secrets scanned with secretlint; AGENTS.md loads at session start with details moved into docs, rules trigger by file path, Skills and Subagents freeze recurring flows and isolate high-volume intermediate output such as review and verification — e.g. a db-reader subagent restricted to read-only by hooks; a five-person team moved from roughly 150 PRs a month to roughly 600): https://tech.plaid.co.jp/claude-code-scalable-team-operation
- [7-92] Safie Tech Blog: "Generative AI adoption: five strategic axes transforming the R&D organization's productivity" (rather than starting from tool selection, the company defined five strategic axes — turning "what we do with AI" into a strategic proposition — and then openly recruited about 20 willing employees into a cross-departmental promotion team, spreading outward from those points): https://safie.hatenablog.com/entry/ai_promoter
- [7-93] TMTPost: "Who really drives AI adoption? OpenAI's platform play, Anthropic's on-site teams, and SANY's self-build — three paths" (SANY Heavy Industry (Chinese: 三一重工) made AI transformation a group-level top strategy rather than an IT side project and created GPO — general business owner — roles: each of four core domains (R&D, supply chain, manufacturing, sales & service) has a senior business leader as its GPO, IT cannot parachute in to take over, and the business decides how AI is used and owns the outcome; the rollout order is deliberately counterintuitive, starting with must-have applications such

as operating dashboards and an after-sales assistant so that real usage drives data collection and standards rather than spending half a year on data first; nearly 600 managers including the entire board went through a closed-door DAMA data-architecture program with unified assessment, which amounts to giving cross-departmental collaboration a shared language; three delivery paths compared — platform-led (scenes stay shallow), on-site FDE (high delivery quality, heavy labor cost, hard to scale), and self-build (autonomous and capability-building but extremely dependent on one operator who understands both business and technology); all three bottleneck on the same thing: people): https://www.tmtpost.com/8038807.html

- [8-96] Lenovo: "Renmin University of China's World-Class Enterprise Research Institute and Lenovo jointly publish The AI-Native Organization Transformation Guide" (five maturity levels: localized "+AI" → broad "+AI" → hybrid AI foundation → "AI+" operational redesign → AI-native maturity; the "golden five-step": top-level planning, value-led prioritization, silicon-based buildout, carbon–silicon fusion, flywheel evolution; three-tier benefits management across scenarios, projects, and programs): https://www.lenovo.com.cn/wiki/article-49384.html
- [8-97] 21st Century Business Herald: "AI-native organizations accelerate into reality as enterprise management keeps evolving" (Chen Chunhua interview: three stages of AI application; AI participates in sensing, deciding, executing; "jobs may fade while roles rise"; super-individuals; the "galaxy structure"; incentives measuring both performance and knowledge contribution; Laoxiangji's AI production scheduling scaled to 400–500 stores, cutting per-store ordering time from 50-plus minutes to about ten; Wens Foodstuff's blind review of AI veterinary prescriptions): https://www.21jingji.com/article/20260919/herald/bcaf0c27d0f60d7058f88f5a93d6c24d.html
- [8-98] China Computer Federation (CCF) Technology Frontier, Issue 178: "AI-native drivers and the rise of super-individuals are reshaping corporate organizational architecture" (the smallest organizational unit is the "human + agent" combination, not a job or an individual; system design takes precedence over model capability; three stages of tooling → agentification → organizational operating system): https://www.ccf.org.cn/Focus/2026-03-20/861614.shtml

- [8-99] Harvard Data Science Review: "The Agent-Centric Enterprise: Where 2–10x Productivity Comes From" (Kruhse-Lehtonen et al., 2026; unlocking 2–10x potential requires redesigning workflows rather than treating agents as accelerators; Linde's audit-report preparation time down 92%): https://hdsr.mitpress.mit.edu/pub/0mrfxamu
- [8-100] Supply Chain Management Review: "From pilot programs to P&L impact in supply chain AI" (failures cluster in process redesign, data integration, and accountability, not algorithms): https://www.scmr.com/article/ai-in-the-supply-chain-from-pilot-programs-to-pl-impact
- [8-101] Stripe Engineering: "Meet Stripe's Knowledge AI Platform" (Kai reached most of the company within two weeks of launch, now 83% weekly active; more than 4,000 micro-agents that became hard to maintain were consolidated into a platform; knowledge work lacks compiler/test/git-style verifiable guardrails; the isolation boundary is task-scoped rather than authorization-scoped): https://stripe.dev/blog/meet-stripes-knowledge-ai-platform
- [8-102] ITValue Summit 2026 closed-door session transcript: "From code generation to organizational restructuring: how AI coding crosses the productivity divide" (Chu Qing: AI is not a tool but a new labor subject; the future organization is a "human-machine union," CHR; all-round capability regression after nearly all code became AI-generated): https://www.ichaoqi.com/guandian/2026/0922/87577.html
- [8-103] InfoQ: "Cold reflection amid the agent frenzy: why scaling always stalls" (Tencent Cloud Agent Runtime; agents differ fundamentally from microservices and databases across elasticity, operations, and governance, requiring a purpose-built runtime): https://www.infoq.cn/article/KmDMAvlzBGgwu5A2kf7t
- [8-104] Umayun: "Enterprise AI agent delivery: the three hidden costs invisible on a 2026 quote" (volatility in model-call fees, context-window inflation, multi-module orchestration and operations; moving from a single-module demo to five to eight production modules makes fault localization grow on the order of N^2): https://www.umayun.com/blog/30170357
- [8-105] Linear: "AI coding has made CI a bottleneck, so we reworked ours to keep up" (after agents sped up shipping, CI became the constraint; the test suite nearly quadrupled while pull-request wait time fell from just over six minutes to just over five): https://linear.app/now/ci-bottleneck-reworked

- [8-106] Korn Ferry: "2026 Talent Acquisition Trends" (84% of HR leaders will use AI more in 2026; its third trend, "cutting entry-level roles equals dismantling the talent pipeline"): https://www.kornferry.com/zh/insights/articles/ai-in-recruitment-trends
- [8-107] PwC China: "2026 Global AI Jobs Barometer," mainland China report (based on more than one billion job postings across 27 countries and regions; introduces the AI Occupational Exposure index, AIOE; skills transform faster than jobs are replaced, with focus shifting from hiring AI talent to raising AI capability across the workforce): https://www.pwccn.com/zh/press-room/press-releases/pr-140726.html
- [8-108] KPMG Hong Kong press release: "Share of organizations with widespread AI adoption rises from 8% to 24%" (recruitment pivots toward revenue-linked roles): https://kpmg.com/cn/zh/media/press-releases/2026/03/kpmg-hk-organisations-focus-recruitment-on-revenue-linked-roles-as-ai-adoption-advances.html
- [8-109] Jinjibu (日本の人事部): "Organizational transformation and the redefinition of HR in the AI era, as seen at HR World Summit 2026" (94% of CEOs will maintain or increase AI investment; about 60% of core business processes could be automated by autonomous agents; Naturgy's controlled study of 300 AI Copilot users against 300 non-users across 25 KPIs: time created per person rose from 121 to 183 minutes per week, output quality up 16%): https://jinjibu.jp/article/detl/attnrept/4116/
- [8-110] TMTPost: "The anxiety sparked by Google's '75% of code written by AI'" (Google Cloud Next 2026: nearly 75% of new code AI-generated and human-reviewed, up from 15% two years earlier; Sonar's 2026 developer survey: 72% use AI coding tools daily and 42% of code is AI-generated or AI-assisted; Faros AI's telemetry across 22,000 developers on the "acceleration shockwave": bugs per developer up 54%, 31.3% of pull requests merged without review; demand for junior developer roles down 67% since 2022): https://www.tmtpost.com/7970697.html
- [8-111] GovInsider: "Singapore gears up to scale the public sector's use of AI agents in later 2026" (GovTech developing an agent registry as part of its AI Assistant Desk suite, so that scale remains manageable and auditable): https://govinsider.asia/intl-en/article/singapore-gears-up-to-scale-public-sectors-use-of-ai-agents-in-later-2026

- [8-112] Reuters: "FTC chair pushes back on treating AI agents as independent actors" (Andrew Ferguson resists anthropomorphizing agents: "if someone tells a tool to do something, and the tool does it," responsibility lies with those giving instructions; audits show systems described as beyond control were executing instructions they had been given): https://www.reuters.com/business/ftc-chair-pushes-back-treating-ai-agents-independent-actors-2026-09-25/
- [8-113] Digital Applied: "AI Agent Productivity Statistics 2026: 100+ ROI Data Points" (citing Gartner: only 41% of agent deployments reach positive ROI within 12 months, and 19% never pay back): https://www.digitalapplied.com/blog/ai-agent-productivity-statistics-2026-roi-data-points
- [8-114] Unlisted.careers: "Ghost Jobs Report 2026-09" (of 607,050 open postings read from employers' own careers sites, 28.3% had been open more than 90 days and 94,106 more than 180 days; median open posting age 36 days; only 14.6% of closures came down within a week): https://unlisted.careers/ghost-jobs/report/2026-09
- [8-115] JOTO AI: "Client case retrospective: key decisions, failure lessons, and reusable methodology from five real AI agent delivery projects" (citing Gartner: 72% of AI projects never truly run after passing the POC; a construction-machinery RAG knowledge base lifting recall relevance from 41% to 91.4%, daily engineer calls from 4.7 to 21.3, first-fix rate up 19 percentage points; 83% of claims rejections at an insurtech traced to conflicts between the rules engine and LLM judgments): https://joto.ai/blog/1790081972149
- [8-116] Oxide Computer, RFD 576: "Using LLMs at Oxide" (Bryan Cantrill; five values in priority order: responsibility, rigor, empathy, teamwork, urgency; argues that disclosure is not always honesty, since volunteering LLM use can be read as distancing oneself from responsibility for the content): https://rfd.shared.oxide.computer/rfd/0576
- [8-117] TMTPost ("Yunqi Strategy Reference"): "Alibaba Cloud CIO Jiang Linquan's 'self-revolution'" (jobs collapsed to PDFE + ABE; the Half-Stack "minimum collaboration unit"; "skill inflation, taste deflation"; effective code per person front-end 3x / back-end 2x; defects per thousand lines front-end -30% / back-end -55%; test coverage 20% → weighted near-100%; the RIDE methodology "avoid failure rather than guarantee success"; "AI is the cherry, the

platform is the cake"; the two hard things in opening the system—permission control and migrating the "fence" of guiding information): https://www.tmtpost.com/8141973.html

- [8-118] InfoQ (compiling Reuters/Wired): "One-year retrospective on Meta's 'OT Project' — code changes up 220% while changes reaching users grew only 36%, major incidents up 40%, firefighting time up 70%" ("OT" = Organization Transformation; some teams slated for a 60% cut, first round about 10%; the CTO's internal figures: code changes +220% / effective changes +36%; AI agents carrying out large-scale destructive operations drove major technical and security incidents +40%; Instagram's zero-authentication password-reset SEV incident; morale fell from 74% to 55%; Zuckerberg canceled the second round of layoffs; the analyst's line "counting predicted capability as actual capacity"): https://www.infoq.cn/article/OCUqGd8wceo7UK23B7NO
- [8-119] IDC: "Agent security: the most underestimated governance challenge in 2026 AI adoption" (about 64% of enterprises have found unauthorized agents or automation scripts running in production within critical business processes; security and ethics the top concern when deploying agents; half of deployers expected to require an AIBOM by 2028; risk stacking across component supply chains, hallucination and goal drift, and prompt injection): https://www.idc.com/resource-center/blog/%E6%99%BA%E8%83%BD%E4%BD%93%E5%AE%89%E5%85%A8%EF%BC%9A2026%E5%B9%
- [8-120] Sonar, "State of Code Developer Survey" (via InfoQ interview): 72% of developers use AI coding tools daily, 42% of code is AI-generated or AI-assisted, 96% still cannot fully trust AI-generated code, and 35% bypass employer-sanctioned tools to use "shadow AI" ("I approve putting this code into production and accept all the risk that comes with it" — the biggest challenge of 2026 is finding someone willing to say it): https://www.infoq.cn/article/e40mGRhF9o583Yi3akyM
- [8-121] Huxiu/InfoQ (roundtable: Kuaishou × Xiaohongshu): "AI code contribution 60%, felt speedup 40% — why did organizational R&D throughput not rise?" (three attributions: the traditional R&D division of labor, information loss as it passes among roles, and business/domain/engineering knowledge not sedimented; Human in the Loop → Human on the Loop; requirement tiers L1–L4; mid-sized teams land it faster; non-R&D staff become the next main user group): https://www.huxiu.com/article/4865678.html

- [8-122] Gartner press release (2026-09-29): "Gartner predicts 70% of enterprises will abandon agentic AI built by vendor forward-deployed engineering by 2028" (costs spiral and the enterprise cannot evolve it on its own; FDE's three phases — before signing, during delivery, and exit and independence; "FDE engagements often fail structurally before they fail technically"; the exit plan must be executed rather than postponed because "the internal team isn't ready"; success is measured not by implementation completion but by whether the enterprise can manage, optimize and scale it itself; predicts fewer than 20% of FDE engagements will convert clients' recurring needs into vendor core product capability by 2028, and warns of "FDE washing"): https://www.gartner.com/en/newsroom/press-releases/2026-09-29-gartner-predicts-70-percent-of-enterprises-will-abandon-agentic-ai-built-by-vendor-forward-deployed-engineering-by-2028
- [8-123] Amazon Web Services Japan blog: "Scaling AI coding agents across teams: a phased environment-buildout practice" (four pains: output quality depends on personal prompting, agents do not follow established development processes, individual know-how is not shared, and review and security verification never entered the system; five steps — make the rules explicit, split knowledge and separate roles, structure the workflow with a four-quadrant asset inventory, add quality gates, and close the learning loop and spread it organizationally; the "before/after the task × human/AI" inventory finds the most-missing quadrant is "mechanical post-hoc verification of AI output"; gates admit only machine-decidable criteria while UX is left to humans; run a fixed "eval set" repeatedly for success rates rather than relying on feel; Hooks record correction instructions at session end as learning candidates and periodically remove scaffolding that is no longer needed): https://aws.amazon.com/jp/blogs/news/scaling-ai-coding-agents-across-teams/
- [8-124] Findy Tools: "The reality of AI coding tool adoption: practical knowledge from seven Japanese companies" (LayerX's "AI trial budget" sits outside departmental budgets and lets ideas be validated quickly outside the normal approval flow; its own Bakuraku virtual cards set per-service and per-person limits with finance settling centrally to contain cost; data-protection-tier usage limits and settings to prevent information flowing into model training are written down in advance; Claude Code's built-in ripgrep was "scarily good" on a 4-million-line monorepo, reaching 80-90% of expectations without elaborate rules;

KDDI's Agile Development Center uses AWS Bedrock Application Inference Profiles for per-person, per-day cost visibility; dely and Aim Sari convinced management with a "bet on the future" rather than strict ROI): https://findy-tools.io/articles/ai-codingtool/88

- [8-125] Tencent Cloud Agent Development Platform (Tencent Cloud ADP): "How enterprises actually take AI agents into production" (four phases — knowledge cold start, workflow orchestration, multi-agent collaboration, and governance and operations; knowledge cold start consumes 40-60% of deployment time; four knowledge failure modes — fragmented formats, splitting disasters, table blind spots, and hard scale ceilings; global intent recognition with parameter rollback; one hotel group's three specialized agents cover 5,000-plus hotels and 20 brands, lifting business-scenario coverage from 75% to 100%, cutting FAQ maintenance from 1,000-plus entries to 100-plus, reducing new store managers' operational error rate by 60% and saving each manager 0.5-1 hour a day; a dairy company's copywriting agent consumes 30 million tokens a day; a logistics customer-service agent consumes 10 million tokens a day; timeline reference: FAQ agent 1-2 weeks, multi-scenario 4-6 weeks, multi-agent 8-12 weeks): https://adp.tencentcloud.com/zh/blog/how-enterprises-build-ai-agents
- [8-126] note (technology consultant suthio): "What changes and what does not when AI coding agents enter the organization" (what changes: the speed of routine implementation and admin CRUD falling to under a third of the time, the quality of juniors' code style, the review lens shifting from naming and style to whether the design can extend, whether boundaries are reasonable and whether the business logic is explained correctly, and hiring shifting from "write this code" to "review this AI-written code"; what does not change: architecture decisions still need humans, inter-team communication cost does not fall and in fact becomes more visible, technical debt does not resolve itself and may accumulate faster, and security review matters more — he saw AI-generated code containing SQL injection almost slip through review because the code "looked tidy"; designing the rules for "what is handed to AI and what must stay human" matters far more than tool selection; "ownership of AI output belongs to the person who issued the task"): https://note.com/suthio/n/nb932191e80d4
- [8-127] Flashcat (SRETALK, author Qin Xiaohui): "In the AI coding era, engineers must learn to manage 'semi-black-box' code with observability" (AI raises the speed of producing code but not the speed of understanding it, so software

becomes a "semi-black box"; observability must move forward from production troubleshooting into design, development, review, canary release and release verification; every important change should ship with observability — critical paths, normal metrics, exception logs, trace branches, business success rates; a release is a controlled experiment; engineers must prove themselves with an evidence chain: release time, error-rate change, P95/P99, where traces stall, anomalous log parameters, config changes, slow queries, dependency flapping; "tests prove it can probably run before release; observability proves it is actually running correctly in the real world after release"): https://flashcat.cloud/blog/ai-coding-observability/

- [8-128] InfoQ (Sequoia Capital in conversation with LangChain founder Harrison Chase): "2026 becomes the watershed for 'agent engineering', and traditional software companies face a survival test" (the behavior of an agent application is not all written in code — part of it comes from the model, a black box outside the code, so the "source of truth" shifts from code to code plus traces; the context at step 14 depends on whatever the previous 13 steps pulled in, and the trace is the only place to see what is actually in context; online testing matters more than offline because behavior only emerges under real inputs; the two hardest parts of harness engineering are understanding what the model was trained to prefer and context compaction; nearly every coding-agent company builds its own harness; memory may become the real moat; "writing code and running code" is more mature than driving a browser directly): https://www.infoq.cn/article/2XfMOshHpdVVKjB2hxms
- [8-129] InfoQ Geek Talk × QCon (roundtable: Deng Lishan of Taobao Shangou, Jiang Tianyi of NetEase CodeWave, Chu Qiushi of Ping An Technology): "The OpenClaw roundtable: SPEC, EARS and guardrails — the boundaries of AI coding, team-level conventions and 'intent-layer' permissions" (the biggest problem with AI coding is not generation but controllability: hallucination, inconsistent tech stacks and poor maintainability; use SPEC to structure requirements, EARS ("when X happens, the system shall...") to standardize them, and ArchUnit/PMD to turn Markdown conventions into executable rules; high-complexity, high-precision scenarios are unsuitable for vibe coding; guardrail one is requirement standardization, guardrail two is TDD/CI enforcement, guardrail three is unified Skills/Lint/CI/Constitution; "the first victims of vibe coding have already appeared

— they need to hire vibe-coding code repair specialists"; in future, writing specs and architecture will be worth more than writing code): https://www.infoq.cn/article/D8E3q93kBviq8Z8mu0Ao

- [8-130] The Information (2026-10-05, relayed by RS Web Solutions) plus the Hacker News discussion (277 points, 276 comments): "Meta and Microsoft take steps to reduce employee usage of Claude and steer them to in-house coding tools" (not skill loss and not a quality problem — more like frontier AI labs dogfooding their own models; when budgets are unconstrained, "tokenmaxxing" really does happen, concerned only with burning as many tokens as possible and unrelated to output; the HN discussion cites a budget of $100,000 per employee per month; one comment nails many organizations' situation: "quality gates keep multiplying until they become a murky pile of actions with near-zero value to the software lifecycle"): https://www.rswebsols.com/news/meta-and-microsoft-take-steps-to-reduce-employee-usage-of-claude-ai/
- [8-131] Criteo Tech Blog (Elise Baturone): "Forever Junior: The Skills AI Can't Develop For You" (what should actually scare us is not software engineering disappearing but senior engineers disappearing, leaving everyone "forever junior"; four self-practiceable skills — curiosity (let the agent quiz you back with Socratic questions), emulation (treat seniors' accumulated review comments as a training set and review the agent's first draft yourself), autonomy (occasionally and deliberately make one small change by hand to rebuild architectural sense, algorithmic understanding and intuition for token efficiency) and collaboration (write the problem clearly yourself before going to a senior); "what agents cannot create is what you choose to do while the agent is running"): https://tech.criteo.com/blog/human-skills-ai-cant-develop-junior-engineers/
- [8-132] Chain of Thought (newsletter): "Software Engineering Is Dead, Long Live Product Engineering" (software engineering was never about writing code but about solving problems with software; the old systems-analyst role returns under the name "product engineer" — translating business needs into software requirements without writing the software; one dataset counts 1,300-plus open FDE-style roles across 565 companies at roughly $240,000 average total compensation; the author expects this role to become mainstream software engineering within two to five years; the junior talent ladder is the biggest hazard — "everyone is talking about high agency"): https://newsletter.chainofthought.show/p/software-engineering-is-dead-long

- [8-133] HackerRank (co-founder and CEO Vivek Ravisankar): "We're sorry we made you grind LeetCode" (acknowledges that technical hiring was standardized into months of problem-grinding that measured interview preparation rather than the ability to build software; three 2026 changes — tasks move from algorithmic questions to real work in code repositories, evaluation from code correctness to "AI fluency and judgment," and the candidate environment from an IDE to an agentic development environment; the agentic interviewer Chakra asks why this approach, what would you change and how the AI-generated code was validated; algorithmic questions still have value but their weight has been repositioned): https://www.hackerrank.com/writing/why-were-sorry

Education (cont.) - [10-249] BNU UNESCO AIED Chair (Ministry of Education case reference): the first batch of "AI + higher education" application-scenario cases (Communication University of China's AIGC; Harbin Institute of Technology's teaching assistant and virtual digital-human teacher; the Open University of China with iFlytek serving more than 3 million English learners a year; Zhejiang University's "Zhihai-Sanle" education model; Huazhong University of Science and Technology's academic-warning mechanism): https://aiedchair.bnu.edu.cn/%E6%95%99%E8%82%B2%E9%83%A8%E9%A6%96%E6%89%B9%E4%BA%BA%E5%B7%A5%E6%9 - [10-250] Trinka.ai: "The rise of AI policy standardization in higher education" (the EU AI Act's high-risk compliance deadline of 2 August 2026; 31 US states introducing 134 AI-related education bills in 2026; UNESCO: 19% of institutions with a formal AI policy, 42% drafting one): https://www.trinka.ai/blog/the-rise-of-ai-policy-standardization-in-higher-education - [10-251] AAUP (American Association of University Professors): "Artificial intelligence and the academic profession" (faculty and staff must have a voice before ed-tech is deployed and in how it is used; proposes an elected "educational-technology oversight committee"; cites the 1966 Statement on Government of Colleges and Universities): https://www.aaup.org/reports-publications/aaup-policies-reports/topical-reports/artificial-intelligence-and-academic - [10-252] Issues in Science and Technology (NAS/ASU): "Community colleges are building the applied-AI workforce" (Miami Dade College's applied-AI associate degree from 750-plus to 2,000-plus students; the National Applied AI Consortium, NAAIC; a "Business and Industry Leadership Team" to identify local hiring demand; faculty expansion of 7 full-time and 20 part-time): https://issues.org/community-colleges-applied-ai-workforce-delgado

Retail & Consumer Goods (cont.) - [10-253] BCG: "How AI is reshaping the retail business model" (the three strategic capability stacks about 70% of above-store employee cost for destination retailers; above-store organizational cost can fall to a tenth; models no longer the bottleneck; the largest workforce transformation since the personal computer): https://www.bcg.com/publications/2026/how-ai-is-reshaping-the-retail-business-model - [10-254] SR Analytics: "8 CPG analytics use cases that deliver ROI in 2026" (Unilever connecting weather forecasts to ice-cream demand sensing with about 30% sales growth in key markets; PepsiCo concentrating on four to five high-conviction use cases; data foundations first): https://sranalytics.io/blog/cpg-analytics-use-cases - [10-255] CMRI (reposting BeautyTech.jp): "NRF 2026: the agentic commerce era and the state of AI" (Google's new protocol; LVMH's "AI for All"; Ralph

Lauren's AI shopping assistant; "humanity takes priority over technology"): https://cmri.itrue.com.tw/2026/03/16/nrf-2026-1 - [10-256] Zhihu (ShopeX / 商派): "Retail brands' AI revolution in 2026: from digital transformation to AI transformation" (three stages: dashboard, assisted driving, full self-driving; three traits of an AI-native retail organization; PwC Strategy&: global retail operating profit +$310 billion by 2030 and margin from 3% to 14.4%): https://zhuanlan.zhihu.com/p/2001979006258534318

Government & Public Services (cont.) - [10-257] Shanghai Institutional Establishment website: "'AI+' empowers establishment management: from experience-driven to data-driven" (a multi-dimensional institutional-adjustment model; a panoramic personnel-structure profile; a "revolving pool" of establishment; the "fixed establishment + AI-efficiency establishment" dual-track; a digital "twin institution"): https://www.shbb.gov.cn/bzglyj202501/9612.jhtml - [10-258] Shenzhen Dapeng New District Government Services and Data Administration: "2025: ten milestones in Shenzhen's digital government and smart-city building" ("Shen Xiao i," the country's first practical public-facing AI government assistant; 45 "handle a matter efficiently in one go" services each cutting an average of 8 steps, 11 days, 4 trips, and 12 documents; talent-introduction household registration from an average of 7 days to under 30 hours, as fast as 24 minutes): https://www.dpxq.gov.cn/dpzsj/gkmlpt/content/12/12626/post_12626700.html - [10-259] Reason Foundation: "Government agencies must be held responsible for negative outcomes from their use of AI" (San Francisco expanding Copilot Chat from a 2,000-employee pilot to nearly 30,000 employees; accountability is not waived by using AI; meaningful human review required): https://reason.org/commentary/government-agencies-must-be-held-responsible-for-negative-outcomes-from-their-use-of-ai - [10-260] Future City @ CommonWealth (CommonWealth Magazine): "Launching Agentic AI organizational change: from process automation to full governance" (a knowledge hub; a "knowledge manager" in each department feeding in process knowledge with answers added within about three days on average; "citizen developers" building five agents a month; process knowledge walks out with the person): https://futurecity.cw.com.tw/article/3943 - [10-261] Infor: "Public-sector AI: accountability over speed" (what really stalls agencies is "operational readiness" — workflows, data, controls, guardrails, and oversight must be in place before an agent acts; citing McKinsey, NASCIO, and MissionSquare): https://www.infor.com/blog/public-sector-ai-accountability

Logistics & Supply Chain (cont.) - [10-262] C.H. Robinson newsroom: "C.H. Robinson showcases its 'Lean AI' build culture at Manifest 2026" and "'Lean AI': hundreds of agents embedded in operations" (450 software engineers and data scientists building in-house; the Always On Logistics Planner orchestrating hundreds of agents; more than 100 trillion proprietary data points; connecting adjacent steps rather than stacking automation in isolation): https://www.chrobinson.com/en-us/about-us/newsroom/news/2026/lean-ai-growing-shipper-impact - [10-263] Flexport: "Winter 2026 release: from a visibility layer to an automation and execution engine" (AI agents auditing customs compliance with error rates down to 0.2%, about a tenth of the industry benchmark; an optimization engine with up to 10% freight savings and in-platform human approval; notification volume down about 80%; the human role moving from operator to approver): https://www.flexport.com/technology/product-release/winter-2026 - [10-264] RELEX Solutions: "The state of supply chain 2026" (67% more confident in AI than last year but only 10% willing to let AI make key decisions without human review and 54% keeping humans in the loop; 71% planning generative-AI investment over three to five years against 32% scaling today): https://www.relexsolutions.com/resources/supply-chain-ai - [10-265] Tencent News (2026 CIFTIS courier area): "YTO, SF Express, and STO show their full-stack AI at once" (YTO's six full-stack achievements: digital twins cutting unloading wait time 25%, the self-built "Zhiduoxing" model driving 100-plus agents, 28 digital employees across ten domains; SF Express's "Baichuan" platform and "Apu AI agent cluster"; STO's "SClaw" platform): https://view.inews.qq.com/a/20260912A04FON00 - [10-266] Chyxx: "Comparing China's listed courier companies in 2026: R&D spending and diverging AI strategies" (JD Logistics RMB 4.136 billion / 1.90%; SF Express RMB 2.96 billion / 0.96%; STO RMB 304 million / 0.55%; Yunda RMB 276 million / 0.54%; YTO RMB 249 million / 0.33%): https://www.chyxx.com/industry/1280132.html

Healthcare (cont.) - [10-267] Tsinghua University (reposting China Youth Daily): "What the AI hospital of the future looks like — the International AI Hospital Consortium Consensus released" (five core traits; "paradigm innovation" as AI-native; "still at the conceptual stage"; "full implementation at least three to five years away"): https://www.tsinghua.edu.cn/info/1182/125144.htm - [10-268] Smart Medical Network: "2026 medical agent white paper: from single AI tools to process-collaborative intelligent applications" (Guangdong's assisted-diagnosis platform across 2,257 medical institutions, more than 270,000 AI-assisted image reads, seven imaging categories above 98% accuracy, hourly read volume equal to 150 tertiary-hospital

radiologists' full day): http://www.cn-witmed.com/list/31/22360.html - [10-269] CCF YOCSEF Hangzhou: "How AI-enabled clinical medicine can complete the last mile" (four blockers: data foundations; technical capability — cross-institution generalization decay and explainability; institutional mechanism — a legal-liability vacuum; commercialization — no mature payment model): http://www.yocsef.org.cn/YOCSEF/Branches/Hangzhou/News/lt/2026-09-26/935369.shtml - [10-270] Berkeley Research Group (BRG): "AI's real disruption: rewiring healthcare operating models" (UC San Diego Health's deeply inclusive governance across IT, HR, physicians, nurses, compliance, legal, ethics, and operations; "AI governance is technical oversight, but even more, organizational alignment"): https://www.thinkbrg.com/insights/publications/ais-real-disruption-rewiring-healthcare-operating-models-2 - [10-271] American Hospital Association (AHA): "2026 Health Care Workforce Scan" (about 40% of surveyed US community hospitals report AI or machine-learning use; leaders rethinking workflows and redesigning care teams; Houston Methodist's computer vision improving operating-room efficiency): https://www.aha.org/system/files/media/file/2025/12/2026-Health-Care-Workforce-Scan.pdf

Manufacturing (cont.) - [10-272] McKinsey Greater China: "State of Organizations 2026: three forces reshaping the future of organizations and nine themes" (15 countries, 16 industries, more than 10,000 executives; the technology wave, uncertainty, and changes in people; first action theme "building an AI-powered organization"; AI as organizational restructuring, not a tool upgrade; the "agentic enterprise"): https://www.mckinsey.com.cn/2026%E9%BA%A6%E8%82%AF%E9%94%A1%E7%BB%84%E7%BB%87%E7%8E%B0%E7%8A%B6%E - [10-273] World Economic Forum (WEF): "3 ways leading manufacturers are preparing their workforce for AI" (AI-driven workforce planning; systematic digital and AI skills training; education-partner talent pipelines; Haier's Chongqing plant using AI-driven key-talent identification): https://www.weforum.org/stories/manufacturing-and-value-chains/ai-manufacturing-workplace-transformation - [10-274] Beijing Daily (京报网): "From tool to employee: Lenovo's AI-native organization case selected for the 2026 enterprise-management best-practices list" (C50+ forum's "annual top ten best practices"; "redefined the organizational paradigm of the AI era and tested AI value by business results"; the shift from "+AI" to "AI+"): https://news.bjd.com.cn/2026/09/15/11959238.shtml - [10-275] PwC: "Agentic AI workforce redesign" (the rise of the generalist; "diamond or hourglass?"; reshaping work with AI rather than merely replacing headcount): https://www.pwc.com/us/en/tech-effect/ai-analytics/agentic-ai-

workforce-redesign.html - [10-276] iResearch: "2026 China Industrial AI Agent Development Report" (the shift from general-purpose agents to specialized-scenario agents; selection criterion moving from model capability to closing the loop on business results; the RaaS model's share): https://report.iresearch.cn/report/202607/4848.shtml - [10-277] Pathnovo: "Why manufacturing AI initiatives fail and how to avoid it" (failures are mostly organizational: no executive sponsor, frontline resistance, unclear ROI, failure to integrate into daily operations; poorly executed AI projects average 15–20% over budget and 6–9 months late): https://pathnovo.com/blog/manufacturing-ai-failures-avoid

Energy & Utilities (cont.) - [10-278] Al Jazeera (citing AP/Reuters): "NextEra to buy Dominion: the ~$67 billion AI-power super-utility" (an all-stock deal serving about 10 million customer accounts; Virginia's largest data-center cluster; contingent on state regulators): https://www.aljazeera.com/economy/2026/5/18/nextera-dominion-to-create-huge-power-biz-as-ai-drives-us-energy-demand - [10-279] Introl: "Microsoft–Constellation restarts Three Mile Island: mapping the nuclear deals behind AI data centers" (Microsoft's 20-year, $16 billion PPA for the 835MW Three Mile Island Unit 1; Google × Kairos Power's 500MW SMR; Amazon's $20 billion-plus Susquehanna conversion; data-center electricity from 460 to 1,300 TWh): https://introl.com/blog/nuclear-power-ai-data-centers-microsoft-google-amazon-2025 - [10-280] Trellis: "Amazon, Google, Meta, and Microsoft go nuclear together" (Meta × Constellation's 20-year, 1.1GW Clinton deal; Deloitte: nuclear can meet at most about 10% of data-center demand by 2035; a single 800MW reactor versus a 5GW data center): https://trellis.net/article/amazon-google-meta-and-microsoft-go-nuclear - [10-281] Bulletin of the Atomic Scientists: "Don't fall for Big Tech's 'nuclear data centers' PR hype" (nuclear commitments under 1% of annual data-center spending; 11,826 data centers worldwide, 4,467 in the US; $17.5 billion in US nuclear supply-chain loans in June 2026): https://thebulletin.org/2026/07/data-centers-powered-by-next-gen-nuclear-dont-fall-for-big-techs-pr-hype - [10-282] Energy Digital: "How Avangrid is implementing AI across its grid operations" (drone inspection, customer-sentiment analysis, grid planning; "First Time Right" built with Amazon Bedrock) and Iberdrola: "How AI is shaping the future of the smart grid" (asset-failure probability prediction, demand forecasting, predictive maintenance): https://energydigital.com/news/how-avangrid-is-implementing-ai-across-its-grid-operations

Professional Services & Legal (continued) - [10-283] Law.com / Corporate Counsel: "Legal leaders have spent years building mentorship programs — the data suggests that isn't enough" (2026-10-09, Women, Influence & Power in Law discussion; technology is compressing the middle of the pyramid as AI, talent and pricing act at once, stripping the traditional structure of its economic basis; years of mentorship investment are not enough on the data, so the development path itself has to be redesigned): https://www.law.com/corpcounsel/2026/10/09/legal-leaders-have-spent-years-building-mentorship-programs-the-data-suggests-that-isnt-enough/ - [10-284] Consulting Magazine: "Scarcity to abundance: how AI is upending the consulting industry's core value proposition — and what to do about it" (2026-10-09; the hourly-billing model is degrading and the traditional pyramid is being upended, because consulting's value was built on trained people being scarce; when knowledge and analysis become abundant, scarcity is no longer where it was — pricing and staffing are two sides of one coin): https://www.consultingmag.com/2026/10/09/scarcity-to-abundance-how-ai-is-upending-the-consulting-industrys-core-value-proposition-and-what-to-do-about-it/ - [10-285] Foley & Lardner: "From AI adoption to AI execution" (2026-10; the firm's own "task-first execution" lens — decide the task first, then the tool, rather than picking a platform and hunting for scenarios): https://www.foley.com/zh/insights/publications/2026/10/foley-at-the-forefront-from-ai-adoption-to-execution/

Media, Content & Creative (continued) - [10-286] BBC Chinese: "Tech executives change their tune: mass layoffs are all AI's fault" (senior executives at large tech companies increasingly name AI publicly when explaining layoffs; analysts note this also signals investors — faced with AI development costs that are real and enormous, executives are not writing blank checks; distinguishing "the reason of technical transformation" from "the reason of financial discipline" matters, since the former maps to process and role redesign over the long term while the latter maps to cost restructuring in the short term): https://www.bbc.com/zhongwen/articles/cn4vwyk3np3o/simp - [10-287] TMTPost: "The illusion and the boundary of the 'one-person company'" (2026-10-10; puts boundary conditions on the popular narrative that AI lets one person run a company): https://www.tmtpost.com/7921071.html

Financial Services (continued) - [10-288] UK Financial Services Skills Commission (FSSC): "A Workforce Transformed: technology, skills and the future of work in financial services" (some roles shrink relatively; industry productivity saw a relative decline of roughly 13-16% after the financial crisis; **the foundation of entry-**

level roles is damaged by AI, which may weaken the talent pipeline; includes Lloyds Banking Group and other practice cases; beyond reskilling, what is needed is redesigning roles and progression paths): https://financialservicesskills.org/wp-content/uploads/2026/05/AI-disruptive-technology-report-workforce-transformed.pdf - [10-289] Digital Bank Expert: "AI reskilling in banking: what most banks get wrong" (the gap is not "training existing staff to do the same work" but "redesigning what people should do and which work does not yet exist"; banks' traditional role architecture (analyst-manager-director) was built around tasks, and AI commoditizes tasks, leaving work that "orchestrates multiple agents, multiple data sources and multiple stakeholders into a coherent output"; new roles include agent operations lead, model governance officer, AI risk underwriter and decisioning systems architect — none of which map onto existing job families, because the shape of the work is different, neither more senior nor more technical): https://digitalbankexpert.com/2026/05/ai-reskilling-banking-workforce-transformation - [10-290] Shanghai Advanced Institute of Finance (SAIF) × Ant Group Research Institute: "2026 Business Evolution of Enterprise-Grade Agents" (judges that by 2026 the global AI industry has fully entered a phase centered on application deployment and commercial closure, with a systematic assessment of the commercial evolution of enterprise agents): https://www.saif.sjtu.edu.cn/sxy_mobile/content/show/107-7061.html

Education (continued) - [10-291] Sohu (reposting an interpretation of Beijing Normal University's "2026 Global Higher Education Transformation Report — Research Report on AI-Driven Innovation at One Hundred Leading Universities"): "Chinese universities' AI projects grow from fewer than 30 to 947" (from fewer than 30 in 2020 to 947 in 2025; AI literacy and AI for Science become focal points; governance questions shift from "should we do this" to "how do we do it compliantly" — scattered projects need unified data, compute and compliance frameworks, and the university-level AI office or committee is usually only truly empowered at this stage): https://www.sohu.com/a/1066407003_121819701 - [10-292] International Journal of Computer Science and Information Security (IJCISIM): "AI-Native University (AINU): a conceptual framework and maturity model" (an academic attempt to move "AI-native" from the corporate context into higher education: AI is not a separate technology or an isolated application but a core institutional capability embedded in teaching, administration and governance; a university-level maturity model must additionally handle the tension between academic autonomy and central coordination): https://cspub-ijcisim.org/index.php/ijcisim/article/download/2999/2379/7289 - [10-293]

Stanford HAI: "2026 AI Index Report — Education chapter" (an annual factual inventory of AI in global education — adoption, policy, investment and capability evidence rather than case studies; usable as a traceable external baseline when institutional claims and vendor material contradict each other): https://hai.stanford.edu/ai-index/2026-ai-index-report/education - [10-294] Sohu (reposting online-education industry analysis): "Online education giant Coursera begins slimming down through layoffs" (in July 2026 Coursera launched its third round of layoffs amid integration with Udemy, expected to incur $8-11 million in severance costs with headcount undisclosed; "every company is telling an AI growth story, but the first chapter of that story is usually layoffs"; edtech layoffs typically carry three causes at once — post-pandemic contraction, M&A integration and AI substitution — which no single announcement unpacks, so research is better spent tracking how functions change after the layoffs): https://www.sohu.com/a/1048113352_354728 - [10-295] Xinhua Daily (authors: Chi Rui, Wang Nianxin): "AI empowerment redefines the value coordinates of university administrative roles" (as AI enters university administration, the value benchmark for administrative posts is redefined): https://xh.xhby.net/pc/con/202606/17/content_1564231.html

Retail & Consumer Goods (continued) - [10-296] Toolio: "Why 95% of retail AI projects fail and what the 5% do differently" (RAND puts overall 2025 AI project failure at 80.3%; MIT (NANDA) says 95% of generative AI pilots fail to scale; S&P Global says 42% of enterprises abandoned AI projects in 2025, up from 17% in 2024; the average failed enterprise AI project costs $7.2 million; only 5% of successful pilots reach production; also cites Pertama Partners putting direct retail AI project failure at 73.8%; the first cause is data quality rather than model capability, and the 5% treat AI as an operations problem rather than a technology problem): https://www.toolio.com/post/why-95-of-retail-ai-projects-fail-and-what-the-5-do-differently - [10-297] National Retail Federation (NRF): "Helping AI succeed in retail: turn pilots into measurable impact" (NRF Nexus 2026, presented by Julie Averill, chief impact officer at Gold Thread LLC and former global CIO of lululemon; cites MIT's "95% of generative AI pilots produce no measurable impact" and RAND's "more than 80% of AI projects fail"; "bigger budgets and more people will not solve this" — the deciding factors are conditions such as culture, human judgment and trust; "culture is not soft — it is the infrastructure the entire organization runs on", and other leaders have to be convinced with measurable outcomes): https://nrf.com/blog/helping-ai-succeed-in-retail-turn-pilots-into-measurable-impact

Government & Public Services (continued) - [10-298] Code for America: "Government AI Landscape Assessment 2026: from readiness to public value" (state government AI adoption is not a procurement decision but an interdepartmental, interagency institutional journey across four stages — readiness, pilot, implementation and impact — and it is iterative rather than linear because the technology moves fast; most states are still early; the key organizational finding — states that establish an AI center of excellence, an enablement lab or a cross-agency committee are better able to scale operational AI, while an infrastructure gap is widening between leaders who build reusable platforms and enablement centers and laggards who work in silos and manage isolated pilots): https://files.codeforamerica.org/2026/04/30110659/government-ai-landscape-assessment-2026-research-report-final.pdf - [10-299] OECD: "Building an AI-Ready Public Workforce" (AI can improve public-sector efficiency and service quality by supporting and accelerating administrative and support tasks, but realizing that potential requires systematically restructuring skills, roles and training to address AI's impact on the civil service): https://www.oecd.org/en/publications/building-an-ai-ready-public-workforce_b89244c7-en/full-report.html

Logistics & Supply Chain (continued) - [10-300] BCG: "Why AI isn't delivering ROI in logistics" (a 2026 executive survey of 30 leading global logistics companies: 97% rank AI a strategic priority, 70% have an AI strategy and 67% have dedicated budget, but only 13% believe AI has delivered measurable financial impact; three root causes — fragmented data, isolated solutions and underinvestment in people; the experience ratio: algorithms are only 10% of the work, technology and data 20%, and 70% is people and organizational change; 37% name "lack of internal AI talent" as the top obstacle; a three-level maturity ladder — Level 1 "AI stalled" (point tools), Level 2 "AI emerging" (tools coordinated within one process, e.g. a customer-service agent calling live rates to complete a quote), Level 3 "AI leading" (a cross-organization connected autonomous enterprise, which nobody has reached); 80% of respondents describe their most valuable AI solution as "a standalone tool"; scale: global logistics revenue is about $5.5 trillion and end-to-end transformation could lift EBITDA by about 5 points, roughly $250 billion of annual incremental profit, about half of it on the revenue side; the organizational prescription is a "federated operating model" — a lean central hub owns standards, platforms and value measurement while business units carry their own P&L — proving "compound effects" in 6-9 months before funding the next wave, with a full roadmap of 18-24 months; cites Gartner's forecast that AI agents will intermediate 90% of B2B purchasing by 2028, and 93% of surveyed

executives already feel threatened by AI-native entrants): https://www.bcg.com/publications/2026/why-ai-isnt-delivering-roi-logistics - [10-301] PwC: "2026 Digital Trends in Operations Survey" (AI-enabled tools are concentrating on core supply-chain activities: planning and forecasting at 66%, sourcing and procurement at 64% — the center of gravity has moved from peripheral pilots to backbone processes, and planning and sourcing are precisely the areas that most depended on veteran planners' judgment and were hardest to standardize): https://www.pwc.com/us/en/services/consulting/supply-chain-operations/library/digital-trends-operations-survey.html

Healthcare (continued) - [10-302] Becker's Hospital Review: "11 lessons from healthcare's first chief AI officers: skepticism, scale and the slow work" (Cleveland Clinic, Cedars-Sinai, UC San Diego Health and others created CAIO roles around 2024; the job is more "chief skeptic" than AI evangelist — Karandeep Singh of UC San Diego Health says the biggest misunderstanding is expecting him to push AI everywhere, when his actual posture is cautious, consensus-driven and "we can try it, and if it doesn't work we stop"; Mouneer Odeh of Cedars-Sinai cites Amara's law — "real transformation is cumulative, not instantaneous"; "data readiness" is the hidden ceiling — prototypes take hours while making the underlying data accurate and outputs reliable takes far longer, and training one EHR workflow agent required reviewing thousands of work instructions accumulated over a decade; Alok Chaudhary of VCU Health spent most of his first 18 months laying the data foundation): https://www.beckershospitalreview.com/healthcare-information-technology/ai/11-lessons-from-healthcares-1st-chief-ai-officers-skepticism-scale-and-the-slow-work/ - [10-303] JMIR AI (Preiksaitis et al.): "Ambient AI documentation and shift documentation time in the emergency department: a 13-month phased rollout study" (extends evidence on ambient AI documentation from outpatient-style settings into the emergency department, a high-intensity, unstructured environment, providing peer-reviewed evidence on whether ambient documentation saves time and where it works better): https://ai.jmir.org/2026/1/e92193

Manufacturing (continued) - [10-304] RSM US: "How manufacturers are using AI in 2026" (RSM survey of manufacturing AI use cases and deployment stages): https://rsmus.com/insights/industries/manufacturing/manufacturers-using-ai-2026.html - [10-305] iFactory (Smart Factory Blog): "Change management and shop-floor resistance in smart factory adoption" (2026; treats front-line resistance as a manageable change variable rather than an execution fault — smart factory programs

stall on change management and workforce readiness rather than on technology selection): https://ifactoryapp.com/industries/manufacturing-plant/change-management-smart-factory-adoption-resistance

Energy & Utilities (continued) - [10-306] World Economic Forum (WEF): "New 'AI application stars' cohort: 26 organizations, more than half from China" (announced June 2026; the 26 organizations span 12 industries and 28 countries; one energy representative is Occidental, which uses AI to give geologists and engineers faster, more consistent subsurface images before drilling begins, reducing costly mistakes and improving drilling decisions; the value lies in where the human-machine division sits — AI works on pre-drilling judgment preparation and the output goes to human experts, matching the sector's general pattern of "AI does the preprocessing, humans sign off"): https://cn.weforum.org/press/2026/06/world-economic-forum-announces-new-minds-cohort-amid-ai-adoption-surge-cn/ - [10-307] CGI: "AI in energy needs to work in operations" (an IT services sector leader arguing AI must work in operations rather than stall in pilots) and POWER Magazine: "Why AI pilots stall: the missing operating discipline" (attributes half-finished trials to operating discipline rather than model capability): https://www.cgi.com/en/blog/energy-utilities/artificial-intelligence-in-energy-needs-to-work-in-operations

Chapters 1-3 (Reports and Data, continued) - [1-42] UC Berkeley: *Measuring Agents in Production* (306 practitioners, 20 enterprise deployments, 26 industries; 73% name productivity as the primary goal, 63.6% reducing manual hours, 50% automating routine labor, with risk avoidance at 12.1% and faster incident response at 18.2%; financial services and banking 39.1%, technology 24.6%, enterprise services 23.2%; 92.5% of agents serve human users directly, 52.2% of them internal employees, and only 7.5% serve other software systems; 66% tolerate minute-level or longer response times; 85% of the 20 deep cases use closed-source models; 70% do no weight fine-tuning, 78% build prompts manually, 12% of prompts exceed 10,000 tokens; 60% said they would use third-party frameworks while 85% of actual teams built their own; 68% run no more than 10 steps before human intervention and 47% fewer than 5, 80% use predefined static workflows; 75% use no public benchmarks, 74.2% rely on human-in-the-loop validation, 51.6% use an LLM as judge always with human spot checks; top challenge reliability 37.9% vs compliance 17.2% and governance 3.4%): https://arxiv.org/abs/2512.04123 - [1-43] World Economic Forum (Chinese edition): *Entry-level hiring down 80% per quarter: AI is dismantling the ladder that produced managers* (written by Cornerstone OnDemand's chief people

officer, citing Harvard research: junior employment fell 9% at firms adopting generative AI, and entry-level hiring per quarter has dropped 80% since 2023; ZipRecruiter's 2026 graduate employment report shows the entry-level share falling from over 44% three years ago to 38.6%; in Cornerstone's survey of 2,000 employees, 38% of Gen Z say AI has fundamentally changed the capabilities their jobs require, while 59% of Gen Z AI users say their organization never provided formal training; the author argues for converting AI-taken tasks into "judgment loops" and rebuilding apprenticeship): https://cn.weforum.org/stories/artificial-intelligence/ai-leadership-crisis-gen-z-cn/ - [1-44] Harvard researchers Fiona Chen and James Stratton using Jellyfish data, reported by Ars Technica: *AI coding agents generate more code but not more software* (sample covers more than 700 software firms, over 700,000 employees and roughly 300 million work events from 2021 through March 2026; after coding agents were introduced, total lines of code rose 30%, commits 20% and pull requests 23%, while Jira issue and epic resolution rates showed no statistically significant change and work-item size and complexity did not shift structurally; review time rose 49%, the share of pull requests requiring changes nearly doubled and comments per pull request rose 35%; the share of workers performing reviews rose 14% while total active headcount did not change significantly; by March 2026, 80% of firms used some form of AI code review, yet agents produced only 23.3% of review comments and touched 10.8% of pull requests; 95% of firms had deployed coding agents): https://arstechnica.com/ai/2026/10/ai-coding-agents-generate-more-code-but-not-more-software/

Chapter 7 (Cases, continued) - [7-94] Niutoushe (36Kr): *NocoBase: 14 people, no headcount growth, revenue doubled — a counter-consensus experiment* (in the first half of 2026 the company decided to stop hiring and froze headcount at 14; R&D efficiency estimated at roughly three times the previous level with the vast majority of code written by AI; 2025 revenue exceeded RMB 10 million and 2026 revenue had at least doubled, split evenly between China and overseas; after coding tools improved in the second half of 2025 the team debated whether a no-code platform still had reason to exist, returning to why enterprises pay — permissions, data organization, process orchestration, long-term iteration, system integration and maintenance responsibility; the new version provides infrastructure for AI development; some engineers now spend about half their time in customer projects, support staff fix product issues directly, and the development/implementation boundary has loosened): https://www.36kr.com/p/3985358764210946 - [7-95] Cybozu (Tateyama,

engineering manager of the kintone generative-AI team): *How to start collaborating with AI agents as a team* (three moves: verbalize the work and define it as Agent Skills, make the skills a team-shareable asset, and prepare an environment where failure is affordable; delegate whole pieces rather than passing context back and forth, which also forces procedures into documentation and reduces key-person dependence; Agent Skills are essentially Markdown natural-language prompts that non-engineers can write, and including bash commands and MCP tool references raises success rates; sharing runs through a Git repository plus the Claude Code Marketplace with one-command onboarding; the safety net is post-deploy smoke tests, CloudWatch Application Signals SLOs and alerts, and a Dev→Staging→Prod pipeline; unresolved issues are where documentation should live and remote execution beyond the repository; cites Gartner's forecast that by 2030 80% of organizations will shift to smaller, more maneuverable AI-augmented teams): https://blog.cybozu.io/entry/2026/03/02/080000 - [7-96] Juejin (Kuangshi): *ByteDance moves some QA teams onto the R&D job family: the party owning quality is changing* (from September 2026 some test teams began moving QA staff to R&D, with some teams merging the QA and RD tracks outright and the rollout proceeding in waves; the RD track carries higher requirements, some staff must pass a new interview and those who cannot may leave; Ant Group, Alibaba and Meituan made similar adjustments over the past two years — test organizations shrinking, job families merging, quality responsibility moving to R&D; the cause is AI coding lowering the bar for unit tests and automation scripts plus cost control; the substance of the merge is a higher entry bar, from executing test cases to writing code, understanding systems and using AI to work faster): https://juejin.cn/post/7689818941397778478

Professional Services & Legal (continued) - [10-308] AI Vortex: *Harvey review: seats bought, fewer than half used* (Harvey has raised more than $206 million; enterprise seat-based annual contracts at roughly $150–300 per seat per month, with a minimum contract size of about $288,000 a year per its companion piece and no individual trial; firms report 30–50% of purchased seats underused — "200 seats bought, 80 people using them"; on value, a lawyer saving five hours a month at a $200 internal hourly cost is worth about $1,000 against the seat price; a general-purpose model at about $25 a month with structured prompting and review covers 70–80% of research and drafting needs, and the 6–10x gap must be justified by compliance, enterprise controls and workflow integration): https://www.aivortex.io/legal/ai-tools/harvey-ai/ - [10-309] Perspective AI: *Kirkland & Ellis's dual-track AI*

strategy (externally one of the legal advisers most central to the AI economy, with Blackstone alone paying $88 million in 2024 mainly for work steering AI and energy-infrastructure deals; internally it has deployed Harvey across more than 4,000 lawyers and created two dedicated roles, "AI Innovation Advisors" and "Innovation AI Developers," recruiting senior talent directly from Harvey; next step expected to be extending Harvey from drafting and review into client intake, conflicts checks, scoping and engagement-letter generation): https://getperspective.ai/blog/kirkland-ellis-ai-strategy-7b-big-law-leader-client-intake-2026 - [10-310] MN Legal: *A 2026 strategy playbook for AI transformation in law firms* (opens with an invoice: a team works all weekend, two lawyers bill at $650 an hour and record 72 billable hours to analyze change-of-control triggers and uncapped liability clauses; argues for redesigning pricing from hourly to scoped fixed fees or outcome-linked arrangements, staffing away from review-hours-heavy junior ratios toward people who can design workflows, and training plus quality control that specifies which outputs must be human-reviewed; notes that clients already run the same tools for preliminary screening, so quoting by traditional hours charges clients for work that can be automated): https://www.mnlegal.net/insights/ai-transformation-in-law-firms-guide - [10-311] Kangda Law Firm: *Law-firm AI data models through the lens of the 15th Five-Year Plan: the Matthew effect accelerates* (AI in legal services has not spread evenly; through the "data–model" loop it systematically reinforces incumbents — heavier users accumulate more labeled data and scenario knowledge, their models improve and they win higher-value work, while smaller firms that only buy general tools fall further behind; the dividing line is whether a firm can build its own data assets and scenario libraries; the argument is deductive and lacks public quantitative data): https://www.kangdalawyers.com/newsdetail_5314.html - [10-312] Deheng Law Offices: *Multidimensional risk control for law firms in the AI era: on-premise is not the same as secure* (with on-premise model deployment roughly 80% of open-source software contains vulnerabilities, so data security faces greater hidden risk and requires dedicated software supply-chain governance and patch management; risk layers include the boundary between client data and trade secrets, professional liability from erroneous model output, and copyright questions when AI processes legal documents; argues for explicit allocation of responsibility among technology vendors, internal IT and business teams): https://www.dehenglaw.com/cn/newscontent/0006/033734/2.aspx?MID=0875

Financial Services (continued) - [10-313] Financial Digitalization Development Network (reprinted from Qingjinrong, by Li Jingxia): *A panorama of the six largest banks' AI layouts in 2026* (models moving from the substrate to the front office and agents from Q&A to task execution, with data governance, security and talent/organization building accelerating; ICBC's "AI-ICBC" combines the "ICBC Zhiyong" technology base, the "ICBC Data Treasury" data space and three digital platforms (corporate, retail, employee) into a "1+1+3" system; ABC deepens AI-native applications around "service-as-conversation"; CCB advances AI-native agent applications; PSBC builds an autonomous AI-native technology architecture and a "Data for AI" "1+3+6+N" dataset system with more than 60,000 multimodal items labeled and over 28 million high-quality records; Bank of China completes "Zhilan" 1.0 with a unified data architecture around collection, storage, construction, use and management; Bank of Communications proposes AI-native products, services and operating models; key definition: AI-native for a bank "is not one more AI department or AI feature, but a fundamental reconstruction of the mode of production"): https://www.fddnet.cn/2026/jinrongkeji_1008/2756.html

Education (continued) - [10-314] Digital Education Council: *AI in Higher Education Global Survey 2026* (students see a relevance gap between courses and future work while teachers are markedly less worried about outdated content: globally 43% of teachers are not concerned that what they teach will be obsolete by graduation; regional variation is wide — Asia-Pacific teachers feel the greatest pressure to adapt, with 43% saying their content may already be outdated by graduation): https://www.digitaleducationcouncil.com/resource-library-items/ai-in-higher-education-global-survey-2026

Logistics & Supply Chain (continued) - [10-315] DoNews: *JD Logistics' ChaoNao 3.0: AI directing warehousing and delivery end to end* (described as the industry's first industrial-grade application in which AI directs everything from warehousing to delivery; five specialist models — PreX for volume and supply-demand forecasting, OptiX for warehouse layout, inventory allocation and vehicle scheduling, OmniX for image and video recognition, GeoX for computing across addresses, routes and time, plus a coordinated-dispatch module; route planning for hundreds of millions of parcels compressed from minutes to seconds and automated vehicle scheduling at 86%; JD Logistics revenue of RMB 124.7 billion in the half year): https://www.donews.com/news/detail/4/6695891.html - [10-316] The Next Web: *UPS builds a real-time digital twin of its global network, committing $9 billion over five years* (a

real-time digital twin spanning more than 200 countries, air and ground networks and end-to-end parcel flows, refreshed every 10 minutes; alongside an agentic control tower, end-to-end RFID tracking and AI customs clearance that the company says clears 97% of shipments on the first day; the "Network of the Future" program commits $9 billion over five years with an expected $3 billion of recurring annual savings; its Happy Returns unit uses AI against return fraud): https://thenextweb.com/news/ups-ai-digital-twin-agentic-logistics-network - [10-317] Raft: *95% of supply-chain AI initiatives fail; the difference is change management* (more than 95% of supply-chain AI initiatives fail to deliver sustained ROI, traced to organizations underestimating change management rather than technology; about one third of employees admit to having actively sabotaged their company's AI rollout (41% among millennials, 44% among Gen Z); 66% of executives say introducing AI created tension or power struggles and 42% worry it is splitting the company; Gartner: 23% of supply-chain AI projects stalled in 2025 due to insufficient cross-functional alignment; recommendations: assess each team's readiness, start from one high-value workflow, pick first users who are curious about AI rather than the most senior veterans, keep every agent action traceable, reviewable and overridable, and shift metrics from manual throughput to decision speed, exception resolution rate and clearance time; cites Hellmann Worldwide Logistics' CEO saying agentic AI lets the company do 2–3x the business with the same headcount): https://raft.ai/resources/supply-chain-ai-initiatives-fail-change-management

Healthcare (continued) - [10-318] Eastmoney Caifuhao (industry analysis): *Medical AI moves beyond top-tier hospitals into county institutions: the capability boundary expands from imaging reads to the whole care workflow* (the boundary expands to record quality control, assisted consultation, pathology diagnosis, treatment-plan recommendation and literature search, embedded in the full care workflow; Shuyang Hospital in Jiangsu embedded AI clinical decision support into physician workstations with outpatient penetration at 46.1%, a 99.5% closed-loop record quality-control rate and response time cut from 54 seconds to 8; Ruijin Hospital with Huawei Cloud released RuiPath 2.0, which uses a device-cloud split so a lightweight version runs minute-level inference on an ordinary PC, with more than 90 hospitals live and a subscription model lowering first-year investment; four barriers remain: zero tolerance for hallucination, data compliance, the vendor/hospital/physician liability boundary, and an unresolved payment model): https://caifuhao.eastmoney.com/news/20261015205444998905250

Manufacturing (continued) - [10-319] Haier Group official site (remarks at the 26th China International Industry Fair 2026): *Zhou Yunjie: AI without boundaries, manufacturing with roots* (advanced manufacturing shifts from automation to AI-ification, from pursuing certainty of scale to absorbing uncertainty of demand, and from point efficiency to system resilience; the competitive focus moves from "what the machine can do" to "how the enterprise keeps creating user value with intelligent technology"; at the organizational level, "restructure enterprise processes and organizational capability the AI-native way," with the explicit claim that technology upgrading "is not simply stacking tools, but a systemic reconstruction of the mode of production, the organizational model and the logic of value creation"; corporate self-description): https://www.haier.com/press-events/news/20261012_295500.shtml

Energy & Utilities (continued) - [10-320] National Grid Partners: *From emergency repair to prediction: two samples from National Grid and SCE* (the NextGrid Alliance already involves 135 utilities and more than 500 senior professionals across 25 countries; National Grid's asset-strategy team uses Monte Carlo-style simulation to forecast which distribution circuits will fall into the worst reliability band by year end, and because Massachusetts penalizes circuits that come last two years running, getting the list weeks early allows earlier upgrades and vegetation clearance; Southern California Edison is building a grid digital twin and built its own YOLO-based vision model to audit switches on poles, spending roughly $500–700 million a year on tree and vegetation work and working with satellite-data firms on continuous monitoring): https://www.ngpartners.com/stories/by-shun-sakaguchi-national-grid-partners - [10-321] Alibaba Cloud customer story: *China Southern Power Grid's dispatch cloud: 97.63% system-wide load-forecast accuracy* (the dispatch-cloud platform built with Alibaba Cloud from 2018, with AI applications on it raising the national dispatch center's system-wide load-forecast accuracy to 97.63%; forecast accuracy directly determines reserve capacity and spot-market strategy; the organizational path starts from the dispatch center as a strong hub to establish grid-wide definitions and data standards, then spreads to distribution and planning): https://www.aliyun.com/customer-stories/power-industry-2022-csg

Knowledge-Base Material (One Source of This Book's Content)

Much of this book draws from the author's personal knowledge base (wiki). Its original sources include 36Kr, Woshipm, Tencent Research Institute, HBS Working Papers, WEF, Harvard Business Review (Chinese edition), LatePost, Economic Observer, and other public publications. Specific entries are recorded in the CHANGELOG with each version update.

Appendix B: Key Metrics for AI-Native Organizations

> You get what you measure. The measurement system of an AI-native organization differs fundamentally from the industrial-era one: it shifts from "input and activity" to "outcome and value." The metrics below are grouped by purpose, all drawn from the research cited in this book.

1. Organizational Structure Metrics ("What do we look like?")

Metric	Description	Benchmark
Relative team size	Headcount vs peers	HBS: AI-native firms are ~25% smaller (services ~70% smaller)
Engineer share	Engineers / total headcount	HBS: ~13 percentage points higher
Management layer depth	Layers from CEO to frontline	HBS: half a layer flatter; Shmool: 4 layers → 1
Builder-to-manager ratio	Direct producers / coordinators	Shmool: 3:1 → 8:1+
Human-to-AI ratio	Humans : AI agents	WEF: early AI-first organizations exceed 1:10
Information fidelity	Distortion of frontline facts reaching decision-makers	Shmool: ~40% loss per hop → ~95% direct
Decision latency	From problem to decision	Shmool: days-weeks → hours
Meeting overhead	Share of workweek in meetings	Shmool: ~30% → ~10%

2. Efficiency and Value Metrics ("What did AI deliver?")

Metric	Description	Benchmark
Revenue per employee	Revenue / headcount	Klarna: $1.24M (3.6x vs 2022); Shopify: $1.52M; Cursor: $3M–13M
Per-capita growth rate	YoY change in revenue per employee	More robust than absolute value for transformation tracking
Output capacity	Output per unit time	Duolingo: course skills 1,800 → 20,500 per quarter (11x)
Time savings	Task-level time savings	Anthropic dialogue research: ~80% on average
Task-level vs structural gains	Single-step speedup vs full-flow improvement	Task-level 20-40%; workflow redesign 2-10x (Harvard Data Science Review)
EBIT attribution	AI's measured contribution to profit	McKinsey: only 39% attribute any EBIT impact; "high performers" (≥5%) ~6%
1.9x revenue effect	Causal gains from organizational learning	INSEAD/HBS field experiment (treatment vs control)

3. Workflow Metrics ("Did the work actually get better?")

> Principle: measure the whole workflow, not the AI task (Chapter 5, rule 8).

- **Cycle time**: end-to-end from trigger to completion (not single-step);
- **First-time correctness rate**: share of cases done right the first time;
- **Exception rate and exception age**: share of exceptions + how long they sit in queues;
- **Repeat-contact rate**: how often the same issue is re-submitted (the Klarna lesson: aggregate metrics hide collapses in high-value scenarios);
- **Complex/escalated-interaction satisfaction**: tracked separately, never averaged into the overall number;
- **Review time**: human review hours (after AI output explodes, review becomes the new bottleneck);

- **Cost per completed case**: full-cycle cost (inference + integration + ops + QA + human review + retries);
- **Rework rate**: share of AI output rejected/redone;
- **AI confidence and coverage**: AI participation rate and confidence distribution (where do low-confidence cases route);
- **Escalation quality**: whether escalations to humans carry full context.

4. Adoption and Governance Metrics ("Is the organization actually using it?")

Metric	Description	Warning data
License utilization	Active users among those with access	Copilot: only ~1/3 (64% of licenses unused)
Paid/premium conversion	Users paying for AI features	Copilot: 3.4%; Notion AI: >50% paid penetration (contrast)
Four-dimensional success	Adoption / efficiency / quality / satisfaction	Anthropic's official pilot measurement
Shadow AI usage	Use of unauthorized tools	Salesforce: 69% of employees used unauthorized tools
AI value accounting	Finance-led ROI validation	CFO-led validation success 76% vs tech-led 53%
Full-delegation ceiling	Share of work fully delegable to AI	Anthropic internal: most employees say only 0-20%

5. Risk Metrics ("Will something go wrong?")

- **Vendor switching cost**: 19-34% of total deployment cost; only 6% of firms can switch without disruption;
- **Agent-related incidents**: Rubrik: 98% of organizations have experienced a disruptive AI-agent event;
- **Skill-atrophy signals**: employees reporting fewer hands-on practice opportunities; share of exploratory work (Anthropic internal: 27% of AI-assisted work would not have been done otherwise);

- **Employee trust**: share of employees who find AI agents reliable (Asana: only 36%);
- **Data AI-readiness**: completion rate of AI-ready data audits (<20% of organizations consider themselves ready).

6. Meta Metrics (Organizational Design)

- **Competitiveness formula**: talent density × AI leverage ÷ organizational friction (Tencent Research Institute) — measure the three variables separately; cut the denominator before doubling the numerator;
- **Innovation density**: output / headcount (DeepSeek's 160 vs the giants' thousands);
- **Influence spillover**: whether one person makes the team faster (the threshold for a Super-Individual, not personal output multiples);
- **Review signal**: does performance review look at input or output? Is AI usage part of the review? (Shopify and Duolingo already include it.)

Appendix C: Version History and Update Notes

Update Mechanism

This book is a "living book," updated automatically every week:

1. An automated system scans global AI-landing and organizational-change information daily, distills it, and stores it in a knowledge base;
2. Each week, new knowledge-base content is merged into the relevant chapters and the version number is incremented (patch +1);
3. The whole-book PDF is regenerated and synced to the GitHub repository (this repository — note: the Chinese edition is also served on a Chinese-facing website; the English edition is hosted here on GitHub only);
4. Every update is recorded in this appendix and in the repository's CHANGELOG.

Version rules: v1.0.0 → v1.0.1 (weekly routine updates) → v1.1.0 (new chapters / major revisions) → v2.0.0 (full rewrite).

---

v1.0.0 — 2026-08-22 (First Edition)

First edition release: built on the knowledge base's accumulated material (12 core concept pages + 20+ case articles) plus three rounds of deep research reinforcement (international cases / authoritative reports / failure cases & methodology).

- 9 chapters + afterword + 3 appendices;
- Chapter 1: The rise of AI-native organizations (the precise framing of the 95% failure rate + a 515-startup causal experiment);
- Chapter 2: Band-aid AI vs AI-native DNA (including a correction of the widely-circulated Gartner CAIO prediction: "90%" is a misattribution; the actual figure is 35%);
- Chapter 3: The evidence (HBS 26-090 / INSEAD / WEF / Tencent Research Institute / McKinsey / BCG / Microsoft);

- Chapter 4: Rebuilding organizational structure (MarsWave / Shmool / Block / the Organizational Brain / three paths);
- Chapter 5: Redesigning workflows and decisions (9 key redesigns / decision rights table / 90-day cadence / three-tier routing);
- Chapter 6: Incentives and talent (Energy Gold / review reform / four incentive dimensions / skill atrophy / innovation density);
- Chapter 7: Case studies (China: Transn / Huawei / DeepSeek / Jingzhunxue / MarsWave; Global: Klarna / Shopify / Anthropic / OpenAI / Notion / Cursor / Duolingo / Airbnb) + six cross-case patterns;
- Chapter 8: Action playbook (Phase 0-4 roadmap / BCG's three plays / Accenture's three principles / 10-error quick table);
- Chapter 9: Challenges, risks, and the future (four failure cases / six risk categories / three future directions);
- Appendix A: 165 sources (copyright compliance); Appendix B: key metrics; Appendix C: this appendix.
